Applications are invited for a S.R.C. C.A.S.E. studentship tenable from 10th October 1979 to investigate the response of aquatic micro-organisms to stress which is induced by the presence of pesticides; it is intended to use estimates of bacterial activity to monitor these stresses. This is a collaborative project between Dr. J. C. Fry (UWIST) and Dr. N. J. Poole (ICI Plant Protection Division, Jealott's Hill, Bracknell, Berks.). The investigation which involves both field and laboratory experiments will be carried out at both centres. ICI will supplement the SRC studentship with £200 per annum (normally tax free) and will cover the additional expenses incurred while working at Jealott's Hill.

Applicants, who must possess or expect to obtain a first or upper second class degree, should send a letter of application immediately to Dr. J. C. Fry, Department of Applied Biology, University of Wales Institute of Science and Technology, King Edward VII Avenue, Cardiff, Wales CF1 3NU. Each applicant must provide a curriculum vitae and the names of two referees. 2070(F)

**Plant Protection  
Division**

**UNIVERSITY OF READING**

DEPARTMENT OF AGRICULTURAL BOTANY  
S.R.C. C.A.S.E. STUDENTSHIP

Applications are invited for a Research Studentship tenable from October 1, 1979 to investigate the breeding of raspberry-blackberry hybrids of the Logan type, and especially the use of new sources of spinelessness. The project will include chromosomal and genetic studies. The student will spend some weeks to each year at the Scottish Horticultural Research Institute, Dundee, which is the Co-operating Body, and there will be financial support for these visits.

Candidates should have or expect to obtain a good Honours degree in Agricultural Botany or Botany, or a suitable biological degree. The successful applicant will be registered for a higher degree.

Applications including details of academic experience and the names and addresses of two referees should be sent as soon as possible and not later than June 15 to Dr. J. K. Jones, Department of Agricultural Botany, Plant Science Laboratories, University of Reading, Whiteknights, Reading, RG6 2AS, from whom further information may be obtained. 2108(F)

**PRESTON POLYTECHNIC**  
S.R.C. POSTGRADUATE  
RESEARCH STUDENTSHIPS

Applications are invited for S.R.C. Postgraduate Studentships on one of the following topics:

1. Climatic and biotic factors governing the colonisation of timber joinery by micro-fungi;
2. Photosynthesis in algae and bacteria;
3. Energy metabolism: effects of diet and exercise.

Further details and application forms can be obtained from

The Clerk,  
Biology Division,  
Preston Polytechnic,  
Corporation Street,  
Preston PR1 2TQ

Closing date: June 29, 1979.

**UNIVERSITY OF DURHAM**  
ENGINEERING GEOLOGY  
LABORATORIES  
S.R.C. C.A.S.E.  
RESEARCH STUDENTSHIPS

Applications are invited from engineers or geologists holding or expecting to obtain a good honours degree for a project, starting on October 1, 1979, on the effects of ground movements caused by excavation. The co-operating body is the Northumbrian Water Authority. Further information and enquiries to Dr P. B. Attewell, Engineering Geology Laboratories, University of Durham, South Road, Durham DH1 3LE. (Tel: Durham (0385) 64971, Ext: 411) by June 30, 1979. 2121(F)

## FELLOWSHIPS

## EMBO

European Molecular Biology Organization

LONG TERM FELLOWSHIPS IN MOLECULAR BIOLOGY  
AUTUMN 1979 AWARDS

Next deadline: August 31, 1979

EMBO long term fellowships are initially awarded for one year. Applications for a renewal for a second year and subsequently in cases of exceptional scientific merit for a third year are considered.

To be eligible a candidate must hold a doctors degree. Preference will be given to European and Israeli applicants wishing to work within Europe or Israel. EMBO long term fellowships are not, however, awarded for exchanges between laboratories within any one country. Applications for fellowships to be held outside Europe and Israel are considered but they have a lower priority, as do applications from non-European scientists wishing to work in Europe or Israel.

Successful applicants will be notified of their awards on October 29, 1979.

Further details and application forms may be obtained from Dr J. Tooze, Executive Secretary, European Molecular Biology Organization, 69 Heidelberg 1, Postfach 1022.40, F. R. Germany. W156(E)

## RESEARCH FELLOWSHIP

A Postdoctoral Cytogeneticist or Molecular Biologist, with experience in human karyotyping, is required to participate in a project on the analysis of chromosomes from human solid tumours.

The appointment is for three years. Salary with entry according to qualifications and experience within range £5,823 to £7,129 inc. L.A. For further information telephone Dr E. Solomons (0865: 511262, ext. 347 until July 1, and then at 01-242 0200, ext. 305). Applications with curriculum vitae and names of two referees should be sent to the Secretary, Imperial Cancer Research Fund, Lincoln's Inn Fields, London WC2, quoting ref. 287/79.

2128(E)

UNIVERSITY OF SURREY  
DEPARTMENT OF MICROBIOLOGY  
POSTDOCTORAL  
RESEARCH FELLOWSHIP

A postdoctoral research fellow is required for a 3-year M.R.C. supported project to determine the DNA sequence of the R46  $\beta$ -lactamase gene. Experience in DNA sequencing or recombinant DNA technology is essential. The starting date will be October 1, 1979.

The salary will be on research grade 1A, starting at £3,883 per annum (under review).

Applications in the form of a curriculum vitae, together with the names and addresses of two referees, should be sent as soon as possible to Dr J. W. Dale, Department of Microbiology, University of Surrey, Guildford, Surrey GU2 5XH. 2089(E)

## ASSISTANTSHIPS

UNIVERSITY OF  
CAMBRIDGE  
DEPARTMENT OF BOTANY  
GRADUATE  
RESEARCH ASSISTANT

Applications are invited for a graduate research assistantship for work on the development and ecological significance of mycorrhiza in seedlings of contrasted types in chalk grassland. The post, which is supported

by the Natural Environment Research Council, is for a period of three years from September 1, 1979.

The salary will be on the scale 1B, starting at present at £3,689 per annum. A suitable candidate would be expected to register for the degree Ph.D.

Applications including curriculum vitae and names and addresses of two referees should be sent as soon as possible to Dr P. J. Grubb, Botany School, Downing Street, Cambridge CB2 3EA, from whom further particulars may be obtained. 2165(P)

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY  
DEPARTMENT OF BIOCHEMISTRY

## POSTGRADUATE RESEARCH ASSISTANTSHIP

A Postgraduate Research Assistant is required to work with an active research group studying pancreatic endocrine function in experimental obesity. The position will be available from mid-July. Previous experience would be welcomed but is not essential.

The starting salary will be within the range £3,718 to £5,333 per annum (according to age and experience) plus £502 London Allowance and U.S.S. benefits.

Applications, including a curriculum vitae and the names of two referees, should be sent, as soon as possible, to Dr Anne Beloff-Chain, Department of Biochemistry, Imperial College, London SW7 2AZ. 2132(A)

CONFERENCE

on

"The Organisation and Expression  
of the Mitochondrial Genome"

Organisers:

A. M. Kroon, The Netherlands,  
and  
C. Saccone, Italy

In the series of annual meetings in Bari, Italy, a conference on the above subject will be held on June 23-28, 1980. Those interested to attend this meeting, which will deal with various aspects of the biogenesis of mitochondria are requested to contact the conference secretariat:

Istituto di Chimica Biologica,  
Facoltà di Scienze,  
Via Amendola 165/A,  
70126 Bari, Italy.  
Tel: 080-339907.The total number of participants  
will be 100. W157(C)

## CONFERENCE

The Sixth Cold Spring Harbor Conference on Cell Proliferation will be held at the Cold Spring Harbor Laboratory from September 4 to 1979. The title of the Conference will be *Viruses in Naturally Occurring Cancers*. For this meeting we plan to bring together leading investigators with diverse backgrounds whose interests vary from molecular biology and genetics to epidemiology.

Topics to be considered include Herpes viruses, papova and adenoviruses, and RNA tumour viruses.

Advance registration is required and attendance will be limited because of space. For additional information write to: Registrar, Cold Spring Harbor Laboratory, P.O. Box 11724, Cold Spring Harbor, New York 11724, or call (516) 692-6660. W167(C)

## Advanced techniques in routine use at The Radiochemical Centre

Described below are just two examples of the many up-to-date techniques, which have been pioneered or applied for routine use at The Radiochemical Centre. These developments are part of our constant endeavour to maintain our position at the forefront of the specialised field of tracer methodology, so that we can continue our supply of radiochemicals of the highest quality and technical specifications.

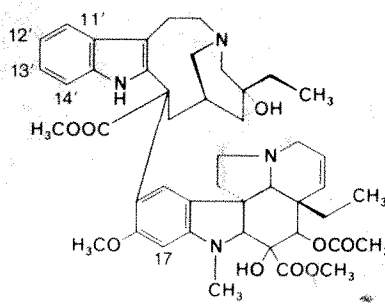

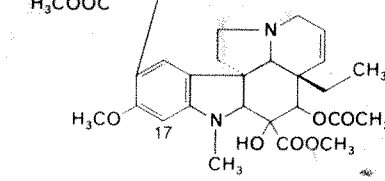

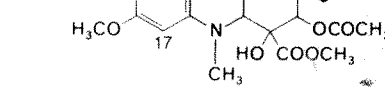

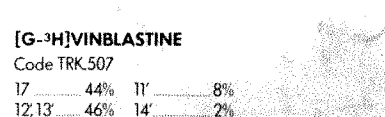

### Distribution of labelling in tritium compounds

Modern techniques for the production of tritiated compounds are more sophisticated than those used in the early days of tritium labelling, and produce compounds labelled in specific positions rather than generally labelled. Nevertheless, it is necessary for many tracer applications of tritium compounds to know the *precise* position and configuration of the tritium labels. Traditional chemical methods of doing this are tedious and time consuming and subject to considerable error, and so the routine supply of such information has until recently not been possible.

The Radiochemical Centre, in collaboration with the University of Surrey, has developed over the past eight years the technique of tritium nuclear magnetic resonance (tnmr) spectroscopy for this purpose. This method is much quicker and more accurate than the traditional chemical or biochemical methods for determining distribution of tritium labelling.

It is now used routinely to establish the distribution of tritium labelling produced by the usual methods of tritiation employed at The Radiochemical Centre. We supply accurate details as to the position and configuration of the tritium labels for an increasing number of our labelled compounds.

A number of examples are given below:

		<b>[18, 2β(n)-3H]TESTOSTERONE</b> Code TRK.162 1αc.....5.9%    2αc.....8.2% 1β.....46.0%    2β.....39.9%	
		<b>[6-3H]BENZO[α]PYRENE</b> Code TRK.501 6.....>95%    1.....<5%	
		<b>D-[2-3H]GLUCOSE</b> Code TRK.361 2(α).....40%    2(β).....60%	
		<b>L-[3,4(n)-3H]VALINE</b> Code TRA./K.533 2.....8%    4.....64% 3.....28%	
<b>[G-3H]VINBLASTINE</b> Code TRK.507 17.....44%    11'.....8% 12', 13'.....46%    14'.....2%

 CHAMBERS, V.E.M., CHAMBERS, V.M.A. and EVANS, E.A.,  
 Steroids vol. 28 (3), p.p. 359-375, 1976.

Circle No. 03 on Reader Enquiry Card.

### High performance liquid chromatography (HPLC)

This relatively new development of column chromatography is carried out using high efficiency microparticulate column packings of closely defined size.

Chromatography is carried out under pressure to ensure good flow rates and reduce diffusion of separated compounds. Dead volumes are kept to an absolute minimum. The result is that many separations can be carried out more quickly and with better resolution than with previously used chromatographic methods such as thin-layer chromatography or conventional column chromatography.

Work aimed at developing the applications of this method to radiolabelled compound separations is still in progress, but The Radiochemical Centre is already using the technique in many of its production processes, and in analytical applications. The result is purer compounds for the customer and greater efficiency of working.

The example illustrated below illustrates the clear superiority of HPLC when used as an analytical tool. The mixture used comprised the tritium labelled mono-, di- and triphosphates of adenosine, cytidine, guanosine and uridine, and all are clearly separated in the HPLC system.

## ANIMAL OPERATING TABLE

- Sterilisable & easily cleaned
- Sturdy but lightweight for effortless handling
- Versatile design
  - table top quickly removed for use without legs
  - height and tilt adjustment for operating comfort
  - suitable for most animal sizes
  - collapsible for storage

Plus a full range of sterilisable stainless steel accessories, cleats and animal support plates. Send for details today.

**NOTE:** To keep animals warm while on the operating table we offer our Homeothermic Blanket System. Details on request.

A four-way electrical socket is fitted to one leg (home market only) plus an earth point on the underside of the table.

### Guide to authors

● Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.

● Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.

● Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.

● 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

**Manuscripts** may be submitted either to London or New York. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the *Système International*. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; exp (*a*) is preferred to  $e^a$  if '*a*' is more than one character.

**References** are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

- (i) only one reference number need be used if the reference is to several papers by identical authors.
- (ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

**Artwork** should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

*Nature's* publishing policy is outlined in 258,1 (1975) and 264, v, 11 Nov. (1976).

## Cuts all round for UK science

In last week's *Nature* (page 565) we were editorialising about the growing weakness in support for R & D in the UK in comparison with other industrialised nations; this is not a weakness of resolve, it merely reflects a weak economy. The first budget of the new Conservative government underlines this weakness—expenditure in the higher education and science area is to be trimmed by between 1 and 1½ per cent as part of a very widespread operation to cut public expenditure.

The past two or three years have seen universities and research establishments pulling gradually away from the times of doubts and instability that characterised the mid-seventies. The University Grants Committee, charged with the responsibility for sustaining universities so that they have (among other things) 'well-found' laboratories in which research councils can support specific projects, has been able to make a little headway in replacing obsolete equipment; the UGC's equipment grant—of the order of £50 million—has even been growing in real terms by 10% annually. The research councils were pleasantly surprised late last year to pick up a promise from Mrs Shirley Williams, then Education Secretary, of £47 million additional cash over the next four years representing annual growth of around 3%. But now the prospects are not quite so bright.

The UGC has been successful in preventing the equipment grant from being cut (although universities will not be immune from the raising of VAT to 15%). But £9 million is being cut from the universities' recurrent grant and capital expenditure is also being trimmed. Nor is this all; there are several university wage settlements in the pipeline, and no guarantee that UGC will automatically receive the additional funds in full to pay for these settlements.

The research councils have had varied fortune. The Social Science Research Council has had nearly ten per cent of its funds taken away, the Agricultural Research Council next to nothing. The Science Research Council, by far the largest, loses £2.6 million of its budgeted £177 million for the present financial year, posing some threat to the 4.2 metre telescope now being planned for the new observatory in the Canaries.

The Medical Research Council might not seem to have come off too badly with a cut of just under 1% in its budget. It employs more people than any of the other research councils, however, and like the UGC will have to find money for increased salaries out of a reduced sum.

Scientists at the MRC units have been aware of this problem since early April when the previous government allowed a 5% increase in salaries in the unit's budgets for the 1979-80 financial year. Salary increases have been averaging at 15%, however, and many research units have been economising on new equipment whilst waiting to see what the new government had in store. With no increase in budgets for the units, the outlook was bleak; with a small cut it is bleaker still. Savings on equipment cannot continue indefinitely so posts will almost certainly be frozen and the already difficult problem of providing a reasonable career structure for scientists will be exacerbated.

It is clear that the cuts just announced do not represent any sort of detailed policy statement from the government on how it will pursue the support of science (with the possible exception of the social sciences). There is much nervous looking forward to the autumn, now thought to be the earliest time that the Department of Education and Science will reveal whether there are to be any major shifts in policy. There are relatively few straws in the wind, beyond that the government is involved in a 'quango' hunt at the moment. Quasi-autonomous non-governmental organisations (the UGC and research councils are amongst them) are said not to be terribly popular and there are moves afoot to trim them in various ways.

Those with memories of the way in which the Labour government of 1964 revamped the administration of science and technology will contrast the planning done by Labour in opposition with an apparent lack of preparation of science and technology policy by the Conservatives prior to this election, leading to a long period of waiting before policy surfaces. This is a disappointment; arguably science and technology policy is more important in 1979 than it was in 1964—even if there are few votes in it. □

# US Defense Department destroys evidence of Vietnam devastation

Alastair Hay reports on a row in the US over the loss of photographs used in the much disputed NAS report on the effects of herbicides during the Vietnam war

PHOTOGRAPHIC evidence, used by the US National Academy of Sciences (NAS) for its 1974 report on the effects of herbicides in South Vietnam has been destroyed by the Department of Defense (DoD). According to Dr Thomas Dashiell, staff specialist for chemical technology at the DoD, the photographs were destroyed "in late 1977 through the spring of 1978".

Estimates of the acreage of forest sprayed with herbicides and the number of trees killed as a result of the spraying were based on these aerial photographs. Hundreds of rolls of film for the period 1958-1973 were examined by the Academy in order to assess the extent of the damage. Dr Philip Handler, president of the NAS, told *Nature* that most of the photographs were "taken by or in co-operation with the Department of Defense and were studied at the College of Forest Resources, University of Washington".

Dr James Bethel, Dean of the College of Forest Resources, was in charge of that study. His initial estimate of "merchantable timber" killed by herbicides was considered too low by a review panel and the figure was revised upwards before the NAS report was published. The report estimated that some  $5 \times 10^5$  to  $2 \times 10^6$  cubic metres of merchantable timber had been killed out of a total of  $8.5 \times 10^6$  cubic metres sprayed. Spraying had in fact affected 10.3% of inland forests, 36.1% of mangrove forests, 3.2% of cultivated land and 5.5% of other vegetation.

Publication of these figures by the Academy created a storm of protest in scientific circles. Accusations that the estimates were too low were made by several scientists. Two members of the NAS committee reviewing the herbicide issue, Professor Paul Richards of the University College of North Wales and Professor Pham-Hoang Hô, University of Saigon, both dissented from the report on these grounds. Hô claimed that the estimates were out by an order of magnitude, a view which was supported by Professor Mathew Meselson of Harvard University and a member of the report's review panel. Meselson also claimed that the figures were 10 times too low.

The charges that the estimates were inaccurate were rejected by the NAS committee chairman, Professor Anton

Lang of Michigan State University. His reply to Hô's dissenting letter considered it "quite impossible" that the figures in the report could be out by the order of magnitude suggested.

Few NAS reports have created as much discord as this one. For this reason alone, many scientists argue that the evidence used by the NAS for the compilation of its report ought to have been kept. Dr Dashiell disagrees. He told *Nature* that the Department of Defense feels that "the NAS committee report represents a complete and well documented analysis of any ecological or environmental effects to the forests in South Vietnam". This, he says, was the principle reason for the study, and the photography provided for the committee study "represented only one means to reach their conclusions".

Dashiell says that the photography was kept for a longer period than originally envisaged. Following publication of the report, the photographs were placed in a repository at the University of Washington for use by scientists interested in doing further work on them.

This arrangement was approved by Dr Handler for the NAS, with the provision that a review be conducted after 12 months to determine whether the material be retained or destroyed. In the event, Dashiell points out, the material was left in the repository for two years, after which it was returned to the DoD where it remained for a further year before being destroyed. According to Dashiell, the scientific community "showed no interest during the lengthy time allowed for any review of their effort".

There is one scientist who was interested in these photographs and who is incensed about their destruction. Meselson, an outspoken critic of the NAS report, is in the process of compiling his own report about herbicide damage in Vietnam. In 1970, Meselson led a team of scientists to Vietnam on behalf of the American Association for the Advancement of Science (AAAS). Government officials in the White House, State and Defense Departments had advance warning of the team's preliminary report to the 1970 December meeting of the AAAS. A short time after this, an order was issued by the White House curtailing the use of

"It means 'Destroy Offensive Documents'!"

herbicides in Vietnam.

A summary of the AAAS findings were published in the Congressional Record on 3 March, 1972, but a final, fuller report of the team's investigations has never been written. Meselson has been chided in private on this point, but he told *Nature* that he hoped to be able to write the report this summer. One of the reasons for his delay was that he wanted to see the controversy surrounding the publication of the NAS report die down. This, he hoped, would give him an opportunity to produce his own report challenging the NAS estimates of timber damage on purely scientific grounds. Meselson makes no secret of the fact that the DoD's action in destroying the photographs has not made his job any easier.

Another reason advanced by the DoD justifying destruction of the photographs also seems rather lame. Dashiell insists that there were "physical storage problems" with the 35,000 items at the University of Washington repository so the decision was made to return the photography to the custody of the DoD. The story as related by Bethel at Washington University is slightly different. Bethel makes no reference to storage problems but says that, as no inquiries had been received about the photographs, he was "instructed by the Academy to return the photographs to the Department of Defense". According to Bethel, it was his understanding that the material was to be destroyed.

It seems, however, that although some probably irreplaceable scientific evidence has been destroyed, all is not lost; according to Dashiell, when the photographs were destroyed, the silver was recovered in accordance with "legislative mandates"! □

# California set to cash in on British discovery

LAST month the Scripps Clinic and Research Foundation in La Jolla, California, announced that it is going into partnership with the pharmaceutical company Miles Laboratories to provide laboratory testing services and prepare immunochemical materials for research scientists and biochemical manufacturers.

The new company will have a staff of about a dozen scientists and will also be able to call on the services of over 150 scientists at Scripps on a consultancy basis. It will offer a range of testing services and products in immunology, endocrinology and toxicology. And one of its most active fields promises to be the rapidly-growing area of monoclonal antibodies. These are antibodies produced by a technique developed a few years ago by Dr Cesar Milstein and Dr George Kohler at the Medical Research Council's Molecular Biology Laboratory in Cambridge, UK. It allows antibodies tailored to identify specific antigens to be produced in relatively large quantities, avoiding many of the uncertainties involved in conventional techniques of antibody production from animal serum.

Already the availability of these techniques and the resulting antibodies has led to what one observer describes as a virtual explosion of interest by research scientists. This has been paralleled, almost simultaneously, by the growth of commercial interest in what promises to be a lucrative range of applications. But although the original research was funded by the British taxpayer, for one reason or another, the National Research Development Corporation did not take out early patents on the techniques and the UK may therefore have forfeited any royalty rights which, some observers believe, could eventually have totalled hundreds of thousands of pounds.

The technique which the Cambridge scientists developed involved fusing two cells, one—taken, for example, from the spleen of a mouse—that produces a range of antibodies (but would be relatively short-lived) and the other a rapidly reproducing tumour cell. The resulting hybridoma cells are separated according to the particular antibodies that they produce, and each cell strain can be cloned to produce a pure source of a single antibody.

For scientists, the use of monoclonal antibodies as a labelling technique (since each antibody will only recognise a particular molecule) is proving to have a wide variety of uses. These range from studies of the structure of cell membranes, to the search for viruses that may be associated with the growth of tumours.

**Has Britain lost large potential royalties through a failure to recognise the commercial potential of antibodies?**

**David Dickson reports**

Commercial interest in potential applications has been equally swift. The most immediate applications lie in the field of screening, for example in the early detection of cancer, or of foetal abnormalities (since foetal cells can be identified at an early stage in the mother's blood by looking out for genetic material from the father). Other uses range from tissue typing to assisting in the search for new vaccines.

Recognising the great potential of monoclonal antibodies, many large medical instrument and pharmaceutical manufacturers are now eager to enter the field. Some have been working on the techniques in their own laboratories; others—as with Miles Laboratories—by tapping into the expertise of the academic community.

"The type of work which we will be doing in this field will be dictated by the needs of the complex of companies under the Bayer (parent company of Miles) umbrella, for which we will carry out research on a contract basis," says Dr Ernest Tucker, director of Scripps' Immunology Reference Laboratory, which will be a division of the new company.

"These companies will come to us with specific needs for antibodies. And since we are an independent company, we will be able to carry out research at the request of other companies too. It is much more efficient to do it this way, since the support of basic research is very expensive."

As well as established companies, the applications of monoclonal antibodies is also attracting the interest of the venture capital market, a booming business in the US following recent changes in capital gains tax and security laws. Like recombinant DNA research, it is a field ripe for swift marriages between sophisticated science and ambitious entrepreneurship but the pay-offs seem at present to be much closer to fruition, while at the research level at least, the field is relatively free of federal regulations.

A typical creation of the entrepreneurial spirit is Hybritech Inc., a company set up in San Diego earlier this year by the west coast venture capital firm Kleiner and Perkins (which also provided much of the initial capital for the genetic engineering firms Cetus and Genentech).

Hybritech has already announced

plans for producing and marketing antibodies for detecting hepatitis, a first foray into a clinical diagnostic market where current sales, according to Hybritech president Howard F. Greene, are around \$200 million a year, and expanding rapidly. Mr Greene predicts that the return on investment for successful research could be as much as five times higher than that in the electronics field. "Already about 90% of the major companies in the diagnostic business have called us, expressing an interest in our work. They are all at various stages of looking at programmes in this area, but the feedback seems to be that the large corporations are not moving with the speed and flexibility made possible by venture capital operations," Mr Greene told *Nature* last week.

The growth of demand for monoclonal antibodies has caused its own logistical problems within the scientific community. Many laboratories offer the hybridoma cells that they have developed to other research workers in the field on request, but this is consuming a large amount of time and energy.

Pressure is now growing for a centralised store of characterised hybridomas. Already a number of cell centres, such as the cell distribution centre at the Salk Institute in San Diego, have a growing number of such cells on their lists. Some scientists are now calling for a new centre, possibly financed by the NIH, to store and distribute hybridomas.

"What seems to be needed is a central depository which would maintain cells that have been carefully characterised and presented by research workers, thawing them out occasionally to check that the characterisation has been maintained," says Dr Hilary Koprowski of the Wistar Institute in Philadelphia. "The time seems ripe for a conference of people interested in the organisation of such a depository, deciding what types of cultures should be accepted, how they should be characterised, and so on."

One problem that a depository would have to face, however, is how it should deal with requests from private companies. With substantial profits looming on the horizon—"Somebody is going to make money in the diagnostic business from this technique," says Jerome Goldstein, head of the Clinical Assays Division of Baxter Travenol Laboratories—licensing of hybridomas promises to become a lucrative business.

At Stanford University in California, scientists who have provided hybridomas to Salk's Cell Distribution Center have required that any research

workers requesting a sample of the cells sign a waiver promising not to use the cells, or the antibodies produced from them, for commercial advantage. The university itself is currently negotiating with a number of pharmaceutical and medical instrument manufacturers on terms for supplying them with specific hybridomas and antibodies developed in the university laboratories. Dr Neil Reimers, head of the university's technology licensing office, sees that as providing the university with a steady

stream of income under an arrangement agreed with the National Institutes of Health, which provided much of the funding for the original research.

Whether or not Dr Milstein's original work in Cambridge could have been patented is still hotly disputed. Some claim that, as the application of standard cell fusion techniques is in wide use around the world, there is nothing inherently patentable about Dr Milstein's use of the hybridoma (although novel hybrid cell lines result-

ing from the techniques can, it is generally agreed, be patented).

Others, however, feel that as a sufficiently novel application of the techniques, a patent might indeed have been granted, requiring royalties to be paid to anyone using the techniques for commercial purposes.

But the net result is that, like penicillin and other similar stories, monoclonal antibodies may join the list of the ones that got away from the UK. □

## Italy's nuclear supremo goes for alternatives

The new chairman of Italy's nuclear energy committee plans to spend as much on alternative sources as nuclear power, writes **Robert Walgate**

For the first time in its history, the Italian National Committee for Nuclear Energy, CNEN, has received money to spend on the research development and promotion of alternative (non-nuclear) sources of energy. On 28 May, the outgoing coalition voted 5 billion lire (about £3 million) to CNEN to spend mainly on solar and wind power and on energy conservation.

The initiative is the work of CNEN's new Chairman, appointed on 1 February, Dr Umberto Colombo, previously research director of the firm Montedison. Colombo joined CNEN on condition that alternative sources would be included, and the 5 billion lire, he told *Nature* last week, is only the beginning.

"In Italy there has been no focal point for an energy policy" said Dr Colombo. "We want to become the focal point for all sources of energy which are alternatives to hydrocarbons."

At present, three ministers have partial responsibility for energy policy in Italy: the Minister for Industry supervises CNEN and the Ente Nazionale per l'Energia Elettrica (ENEL), which has responsibility for electricity supply; the Minister of Culture and Scientific Research directs the central body organising basic research in Italy, the Consiglio Nazionale delle Ricerche (CNR); and the Minister of State Participations has responsibility for the Ente Nazionale Idrocarburi (ENI) and the Istituto per la Ricostruzione Industriale (IRI); all of these being bodies with a more or less great interest in energy policy. The Minister for Industry has the largest responsibility—establishing the national energy

Colombo: "We might even be able to do without fast breeders"

plan, versions of which were published in 1975 and 1977.

"I want to make CNEN the entity responsible for all alternative sources, so that ENI remains responsible for fossil fuels, ENEL for electricity, and CNEN for R & D and promotion of nuclear and non-nuclear alternative sources, including the most important alternative—energy conservation."

The CNR is also undertaking an energy research project, but Colombo does not foresee conflict, rather co-ordination: "CNR is more involved universities; our contact is more with fundamental research and industry". ENEL and ENI have large geothermal projects "so we won't be able to do so much on that—probably we'll concentrate on hot rocks".

Dr Colombo hopes to make a substantial investment in non-nuclear alternative sources. The CNEN budget for 1979 is 200 billion lire (about £115 million), of which there is only 5 billion lire for alternatives; "but since we have only just started we could

hardly be expected to spend much this year". Next year, Colombo hopes to spend 30 billion lire (£17 million) on alternatives, and ultimately to reach an expenditure "very close to what we shall be spending on nuclear power".

Would it be possible to spend that much on new sources? "Well if you take some pioneer projects, and you consider that we are not interested so much in basic research as in demonstration units—in conservation, solar, wind, and so forth—it's possible". Clarifying the point, Dr Colombo said he has in mind an ultimate allocation of resources similar to that of the Department of Energy in the US, where nuclear—including fusion—still has more than other sources, but alternative sources have a substantial portion of the budget.

Nevertheless Colombo is convinced that nuclear power must make an increasing contribution to Italy's energy supply; at present one major and three minor reactors supply 0.7% of Italy's total energy needs and 2.7% of its electricity. By the year 2000, Colombo would like to see 20% of Italy's energy needs supplied by nuclear reactors requiring a building rate of two reactors per year; solar power, the main alternative contributor, might supply 7% by that date, he estimates.

"We do not have North Sea oil, we do not have the gigantic coal fields you have in the UK; at present we are very dependent on imported hydrocarbons. 85% of our energy is supplied by hydrocarbons, and 76% is imported energy. This dependence is not acceptable; we are very vulnerable. Our oil bill may go up this year, because of the price increases, by £1 billion; that's equivalent to exporting another million automobiles, if we want to keep our balance of payments in order . . . so a nuclear programme, as well as a vigorous programme on alternatives, is necessary for Italy."

Colombo makes a fairly classical connection between energy consump-

tion and economic growth. After conservation measures have been applied, he estimates Italy will be consuming 40% more energy in the year 2000 than now. "Don't measure that against UK standards. Our per capita consumption is 2.4 tonnes of oil equivalent; you have 3.7; so we must make great progress to reach other European countries. We can't possibly stay much behind them if we want to develop our own industry." The 40% increase corresponds to an annual rate of about 1.4%, and is based on an assumption of economic growth of 2.5% per year with an 'energy elasticity' (ratio between energy and economic growth rates) of some 50%.

Colombo is in the process of constructing his first 5-year plan for CNEN. "In the past everyone has been very superficial: both parliament and government, and CNEN, ENEL and the industry." Now Colombo believes that "we at CNEN must express our opinions forcefully, justify them with numbers and facts, and submit our ideas to a discussion in parliament." Then it is a matter of responding to the political will of parliament and government. Colombo hopes to submit his plan by the end of the summer.

Previously CNEN's energy policy was "very much in the air, something rather abstract". CNEN was moving in many different directions, in each of them "below the necessary threshold" of potential, manpower, and capital. Furthermore CNEN has been hampered by the government's inability to define a politically and publically acceptable nuclear plan. But in any case the previous plan "was too ambitious, and not credible at all".

"There were gigantic plans to build up a huge number of power stations, but the plans were never implemented. . . . They required almost a menu of different nuclear technologies, which—particularly after the Harrisburg incident—is no longer advisable. We need to concentrate on one type of proven reactor, and to put a great emphasis on the safety and security aspects of that one. I therefore will use my influence and my power—as far as possible—to determine this concentration of effort on one type of reactor. I do not think we have the technical or organisational capability to go ahead in many different directions in nuclear power in Italy."

The reactor will probably be the Westinghouse pressurised water reactor, which has also been chosen in France and Germany; this not because Colombo has any particular attachment to that but because the concentration of international effort and experience on it should make it one of the safest systems.

Nevertheless the Italian industry will continue to work on other reactor

systems, like the Tirrhena heavy water reactor presently under construction "to enable the industry to work on the commercialisation of CANDU-type reactors throughout the world". CNEN will also do direct and sponsored research and development of fast breeders and fusion reactors.

On nuclear safety, CNEN is at present both promoter and regulator of nuclear power—an unsatisfactory situation which Colombo expects to be changed sometime next year. At present "they both depend on me" says Colombo. But for the moment he is reluctant to give up the dual role. "We must first make the safety division of CNEN stronger technologically; I want to fortify it a little bit before giving it to somebody else. Secondly, the safety problem in nuclear plants is not just a health problem, it's a matter of checking the design, construction, and operation of very complex technological plants, which requires some technical expertise. If safety is left in the hands of medical people alone, and epidemiologists, they will cover very well the biological part but won't be competent in the other. So we need both, and we need to move towards the creation of an independent organisation. I hope it will be constituted under the premier, who controls both industry and health, allowing the organisation to include both types of competence".

"I am grateful to those who have been against nuclear power, although I do not share their ideas" said Colombo. "They have brought the problem to the surface, and obliged us to be more frank and serious in our considerations." In the past, he said, the nuclear authorities in Italy have been too arrogant in their dealings with the public; it is time to consider clearly and openly all the risks, both with and without nuclear power.

Furthermore, "if we are able to develop alternative sources immediately so that they can penetrate by 7% by the year 2000, and take off thereafter, we might even be able to do without fast breeders. But if the rate of penetration is slow, and if nuclear fission is the bridging energy source up to 2020–2030, we will have serious problems with uranium."

Colombo therefore wants to keep fast breeders open as an option, and Italy is already building pilot reprocessing plants "so that when we have to decide, we can decide from a strong position".

Ultimately, however, it is all up to the Italian government. "I'm powerful as far as propositions are concerned" says Colombo "but I'm not the one who decides". Colombo will be submitting his first 5-year plan to the government "in a month or two". □

## Energy efforts should shift from research to conservation

THE US Administration is placing too much emphasis on research into new energy technologies, and not enough into conservation techniques even though the latter have already produced considerable energy savings, according to a paper published by the Union of Concerned Scientists.

Dr Vince Taylor, the author of the paper, points out that improvements in efficiency made by industry since 1973 have contributed twice as much as oil obtained through the Alaska pipeline to the energy needs of the US last year. "90% or more of the solution to our energy problems will come from improvement in energy productivity—10% or less from supply extension. Yet the administrative and budgetary resources are being allocated in just the opposite proportions," Dr Taylor writes.

Dr Taylor lays out what he calls an 'easy path' strategy which, he claims, would redress imbalances in the energy budget by concentrating on factors such as improving the efficiency of motor vehicles and of energy use in domestic and commercial buildings, and selective switching between fuels. This strategy, he says, does not depend for its success on expensive and uncertain long-range R & D projects. □

## Carter proposes new fund to clear up chemical wastes

PRESIDENT Carter has submitted to Congress legislation setting up a \$1.6 billion fund for cleaning up hazardous chemical waste dumps and the effects of chemical and oil spills, in what one aide has referred to as "the most important environmental legislation" to be proposed by the Administration in the current year.

The President's move has been prompted both by general concerns about the effects of industrial pollution, and more specifically by a number of recent highly-publicised cases in which the previous dumping of toxic wastes has led to serious environmental and health hazards.

Against the advice of a number of federal agencies (although not the Environmental Protection Agency) the President has also decided that the industries responsible for the wastes should carry a large part of the bill for clearing them up. Consequently 80% of the fund would come through a series of fees imposed on oil refiners and chemical manufacturers. □

# Whitehall urged to relax grip on research funds

THE UK Agricultural Research Council is now poised to gain control of £2½ million of its funds previously tied to work commissioned by the Ministry of Agriculture, Fisheries and Food (MAFF). And this desire for greater freedom from the commitments of the Rothschild reorganisation of research has been reinforced by a plea from the Medical Research Council that Department of Health and Social Security control of its funds be reduced.

Both developments were revealed following last week's publication of the minutes of meetings of the House of Commons public accounts committee. In the case of the ARC it was stated that a review had been carried out by the MAFF and the Department of Education and Science under the previous government and this had investigated charges made by the ARC for use of its facilities. In particular, it was felt that more money should be paid by the MAFF for superannuation of staff carrying out its work and also for some capital costs. The full charges amounted to about £2½ million and it is now known that the Ministry has decided to pay this figure.

Although the MAFF will still control 54% of the ARC's budget, which last year totalled £45.6 million, it will now find £2½ million of its money earmarked for staff and other costs. This will free an equal sum for direct use by the council, which is likely to spend it on priority areas such as the genetic manipulation of plants with the aim of introducing new characteristics in crops.

However, the agreement to charge full economic costing for ARC facilities still has to be confirmed by the new Conservative administration, and this decision is expected shortly. Even when agreed, the effect will not be immediate, as many MAFF projects are being funded over long periods and there is no question of them being abandoned. But in the long term this financial reallocation will certainly give the ARC far greater flexibility in its undertakings.

In his plea to the committee, Dr James Gowans, the secretary of the MRC, said the transfer of its funds to DHSS control represented a vulnerable area in the council's £60 million budget: "It is vulnerable because the rules say the government departments are expected to spend the transferred funds with particular councils, but they do not have to."

He described the present arrangement as not being ideal—a dissatisfaction that stems, in part, from the 1976 cutbacks which resulted in the DHSS suddenly reducing its funding of

the council by 10%. "I should like to enter a plea that the MRC feels a little uneasy about the large chunks of its funds which could with political change be either decreased or might conceivably disappear. In fact, I should like to see in the long term the fraction of my council's total money, which is free money, increase—to give us greater stability and flexibility", he told the committee.

Dr Gowans said there were particular difficulties in trying to direct biomedical research through departmental contracts. One problem stemmed from the MRC's need to supervise all research, from basic to applied.

"In cancer, for example, we would

James Gowans, MRC: "vulnerable"

consider it essential to start with basic molecular biology and go right through to trials of new chemicals and radiation therapies", he added. It was of no use to pick a small fraction of a programme and concentrate only on that aspect.

"The other point is that if one looks back at the history of medical discovery, one finds that the key discoveries have all been made by accident", he stated. This also made it difficult to commission effective pieces of research and Dr Gowans indicated that he would prefer a system of saturating the very best talent with funds, although this would be hard to justify in times of financial stringency when many workers were competing for limited funds.

However, in his report to the committee, Sir James Hamilton, permanent secretary at the Department of Education and Science (which controls the major portion of the MRC's budget) said it would be wrong to suggest the idea of the customer-contractor relationship had failed—although he revealed that the DHSS-MRC relationship will be reviewed this autumn. This is to ensure basic objectives are being met in terms of scientific and financial accountability and are not being unnecessarily burdensome in bureaucratic terms.

Robin McKie

## WHO lays down safety guidelines

THE World Health Organisation is making progress with its attempt to lay down guidelines on occupational exposure to toxic substances. A meeting in Geneva this month agreed on a methodology for arriving at permissible levels of exposure to four heavy metals—cadmium, lead, manganese and mercury.

The first step is to examine all the available medical and scientific information, followed by the decision on what degree of risk can be tolerated. Degree of risk has to be decided at national level, partly because circumstances differ in some countries. For example, in the tropics, industrial workers may also be exposed to endemic diseases affecting the kidneys, liver or lungs. The acceptable level of metals toxicity affecting the same organs would therefore have to be much lower there than in northern industrialised countries.

The meeting made a breakthrough with agreement between the US and USSR on what should be the actual basis for exposure. The Soviets are considering switching to the American system of time-weighted exposure and abandoning their previous "maximum exposure" basis. There has also been

agreement on the principle of adverse health effects" for the four metals under consideration. Two criteria have been laid down: (a) is the effect reversible or not? (b) are compensatory mechanisms in the body impaired? From this it is possible to define the effects of each substance on an agreed "target organ".

Finally, the Geneva meeting agreed on permissible levels for each metal, both "biological levels" in the person affected and atmospheric levels in the place of work or in the immediate vicinity of a plant such as a lead smelter.

The need for guidelines such as these was because of the wide discrepancies in permissible levels between various industrialised countries and the feeling that guidance would help Third World countries moving into industrialisation. Previous attempts to recommend levels of toxicity through the International Labour Organisation have tended to be blocked by employers pressure groups. The WHO approach was specifically medical and scientific, but it is understood there were, nonetheless, messages of strong disapproval from a number of industrial firms.

Peter Collins

## news in brief

**Sussex students occupy physics building:** The protest at Sussex University (14 June, page 568) continued to escalate as students occupied the physics building, which houses the university's main telephone exchange. The telephone service to the university was cut off. The occupation, which began on 15 June and is expected to last for at least another week, is the result of a week's failed negotiations. Students elected the "excluded" student body president Richard Flint and engineering student Shaun Fensom, to present their proposals for joint talks with staff at the university Senate meeting. (Their proposal has been widened to include the case of 305 students threatened with academic sanctions because of a current rent strike against university housing. The students voted that sanctions or threats of sanctions should be withdrawn as a precondition for talks and voted to go into occupation if the amnesty proposal was rejected.

Upon seeing the two excluded students in the meeting hall, Vice-chancellor Denys Wilkinson called off the Senate meeting but was persuaded by moderate staff to reconvene it. A morning session was followed by a massive rejection in the afternoon of the student proposal. There are no immediate plans to call off the occupation and administrative hopes that the summer vacation would dampen opposition were dashed as the students voted to disrupt conferences during the summer at their last general meeting on 19 June.

**Philippines call halt to nuclear plant:** The Philippine government has halted construction work on a £600m Westinghouse reactor for alleged violations of the safety warranty. The plant was begun in 1976 and was to be finished in 1983. The government acted when Westinghouse refused to send a safety team to the Philippines to discuss the Three Mile Island accident, and after the US Union of Concerned Scientists had sent a detailed plan of deficiencies in engineering and design. Westinghouse had commissioned an independent inquiry which found that there was no evidence that the reactor would be unsafe. The ban on building will not be lifted until the government is convinced that the plant posed "no danger to the people."

**Vietnam veterans studied for herbicide exposure:** Vietnam veterans are to be the subject of a study of the long term effects of exposure to the herbicide, 2,4,5-T. The investigation, ordered by the Carter administration, will examine 1,200 veterans exposed to the herbicide during spraying missions over Vietnam in the years 1962-1970. Scheduled to last six years, the investigation will be carried out by the Air Force and the Department of Health, Education and Welfare; it will supplement an inquiry already begun by the Veterans Administration. Concern about the health hazards of 2,4,5-T and its tetrachlorodibenzo-p-dioxin contaminant—a known teratogen and carcinogen—has increased in recent years. Vietnam veterans were exposed to the herbicide in a formulation called Agent Orange of which 2,4,5-T is one of two components. Agent Orange was known to have much higher concentrations of the dioxin than 2,4,5-T preparations in current use.

Clinical data from the 1,200 subjects will be compared with that from a control group of 1,800. Doubts still remain about the scientific methods to be used in the study. Evaluation of the results will also prove difficult with the wide ranging clinical symptoms attributed to exposure to 2,4,5-T. Veterans are claiming that psychological disturbances, malaise and death from cancer can all be traced to exposure to 2,4,5-T.—*from Alastair Hay.*

**New HSE microbiological adviser to be tough on safety:** The UK Health and Safety Executive has appointed Dr Bob Harris (left) as its adviser on microbiological hazards at work. Harris, director of the former Microbiological Research Establishment at Porton Down, is a firm believer that society must control the safety of research work. He also supports trade union and general public representation on committees such as the Genetic Manipulation Advisory Committee. Harris took up his post of senior consultant adviser on 21 May. He will oversee the development of contaminant assays and training of HSE staff in their use, and he will represent the HSE on committees and public bodies. Harris is an experienced cancer researcher, most recently as head of the Imperial Cancer Research Fund's Division of Experimental Biology and Virology. His appointment is expected to silence criticism from "a minority of researchers" who have opposed HSE interventions in laboratory safety.

**British delegation tries to sell Magnox reactors in Peking:**

A British Energy Exhibition organised by the UK Department of Energy and the British Overseas Trade Board visited Peking from 6-16 June to sell energy technology to the Chinese. British Nuclear Fuels Ltd and the Nuclear Power Company are trying to interest the Chinese in the UK's Magnox reactor, an old first generation machine that is considered to be the safest nuclear reactor. Mr Robert O'Neil, head of engineering safety and technology at the UK Atomic Energy Authority, gave a long talk on reactor safety to a Peking conference on 12 June. O'Neil told the Peking audience that the probability of receiving a lethal dose of radiation at a distance of 15 km from a reactor was approximately the same as being hit by a meteorite or "killed in a supernova explosion of a star". There is no record yet of specific questions asked by the Chinese about reactor safety.

**Environmental agency urges destruction of nerve gas bombs:**

The US Environmental Protection Agency has recommended to the Defense Department that it should destroy the Army's stock of 900 Weteye nerve gas bombs, rather than move them from a Denver arsenal to a base in Utah. This follows evidence that a number of bombs are leaking inside their sealed containers.

Although the Army had initially announced its own plans to destroy the weapons (the most modern chemical weapons in the US armoury produced shortly before a ban was imposed by President Nixon in 1969). Defense Secretary Harold Brown announced last year that the weapons would be kept as a deterrent to any use of lethal gas in war by the Soviet Union. Plans to move the bombs, which contain more than 300,000 pounds of gas, were first proposed for last year, but postponed when two were found to be leaking. Following a new announcement last month by the Defense Department that it would shortly begin transporting the bombs after an investigation had concluded that the rest of the bombs were safe and could be moved, Utah governor Scott Matheson announced his intention to seek a court order preventing their transport.

In a letter to the officials of the Rocky Mountain Arsenal, where the bombs are currently housed, the EPA says that, in view of newly-discovered leaks, the bombs should be destroyed.

# CERN—the next 25 years

The European centre for subnuclear physics—CERN—celebrates its 25th anniversary next week. But it is a time for Europe to look forward, not back. **Robert Walgate** reports

AMERICAN high energy physics laboratories—there are three major ones—have generated one or two Nobel prizes, and much spectacular physics. On the other hand CERN, the European centre for high energy physics, has discovered 'neutral currents' (a new kind of weak interaction), but nothing else with the feel of a Nobel prize. (The one for neutral currents hasn't been awarded yet.) CERN has been much praised for the quality of its work; but sometimes this has felt like being patted on the back for trying hard. However, all this seems about to change.

Burton Richer, an American who won a Nobel prize for discovering the  $J/\psi$  (indirectly a discovery of the charmed quark) agreed last week that in the last 25 years the greatest discoveries have been American; but in the next 25, he said, "Europe will become the senior partner". And according to Leon Lederman, also a man of spectacular discoveries (he recently found the next quark, bottom, in a 9.5 GeV particle called  $\psi$ ), "the US is going to have a rather hard time competing".

However "it's nonsense" says Lederman, to say that CERN was too concerned with quality and missed the spectacular results. "Anyone can get spectacular results". The reason the US got most of the big discoveries was partly the statistics of small numbers—luck. "Plus we had a heritage of experience. We had accelerators running in 1951." CERN's first, the SC, started up in 1957. And now he envies the quality of CERN engineers. "The European engineering education is better based in mathematics and physics and ideally suited to accelerators."

Lederman should know, for it is, in some sense, his job to compete: he has been appointed director of The Fermi National Accelerator Laboratory (Fermilab) in Chicago, America's nearest equivalent to CERN. But he says "we're undermanned by a factor of 2 or 3; we don't have the people or the money". The previous director, Robert Wilson, resigned over a question of funding.

But CERN isn't going ahead simply because the US is falling behind. It has three adventurous plans on the books: one approved and building; one on the verge of approval; and one very ambitious scheme yet to be put to the political test.

The first (the antiproton collider) should generate physics from the collisions of protons and antiprotons within the present 500 GeV accelerator ring towards the end of 1981. There's probably a Nobel prize in it through the discovery of the 'intermediate vector boson' (a particle as important to modern physics as the structure of DNA was to 1950s biology). The second (LEAR) should use stored antiprotons for unique experiments in low energy nuclear physics. And the third (LEP) would generate 200 GeV collisions between electrons and positrons (presently the cleanest way of investigating the fine structure of matter) towards the end of next decade. There are probably a few Nobel prizes in that.

A firm and unanimous proposal for LEP, the result of the deliberations of hundreds of physicists throughout Europe in the technical panels of ECFA (the European Committee for Future Accelerators), should go to CERN Council on 9 November this year. LEP is CERN's future for the late 1980s and 1990s; it is up to governments to decide if CERN can have it. (The clash between Germany and CERN over the siting of LEP has died down; CERN will have it, while Germany's national Hamburg laboratory DESY will add protons to its electron rings: at least that's the physicists' plan.)

Hamburg, too, is ahead; experiments are underway there on what is presently the world's highest energy electron-positron machine, PETRA, with the American equivalent, PEP (Burton Richter's machine), coming on in November about a year later because of funding delays.

But America hasn't given up. According to Lederman "I think Fermilab is going to cause CERN a lot of grief". Fermilab is building—and has been building for some time—a ring of superconducting magnets (the 'energy doubler') to join the normal magnets in its 500 GeV proton accelerator tunnel, and these magnets will give Fermilab the capability of reaching beam energies of 1000 GeV to collide with a target, or making collisions between 1000 GeV and 1000 GeV counter-moving protons. Lederman hopes to phase in physics on the colliding beams by 1982; and on fixed target by 1983. This would give Fermilab the highest energies in the world. "The doubler is the only way

Leon Van Hove, CERN research director: leaving "after a very interesting period of defining future projects"

we can get ahead" says Lederman.

(Ultimately the USSR should overtake Fermilab with UNK, a 10,000 GeV—10 TeV—machine.)

Furthermore at Hamburg there have been problems in reaching design collision rates (which determine whether an experiment can be done in months or years) because of a complicated acceleration system which will not trouble PEP. Richter says "I've laid a number of bets that within two weeks of first injection we will be at 10% of design luminosity". PETRA has been sitting around 1%, and although this figure is rising fast there will be a lot of physics left for PEP to do.

A few years ago such competitiveness was justified in terms of repeating experiments: if Fermilab discovered something, then CERN ought to check it. There was an example of that recently, when an anomaly in neutrino interactions discovered in a rough and ready fashion at Fermilab was checked—and discounted—in a more sophisticated experiment at CERN.

## Sharing unique facilities

But the future seems to be one of unique, continental facilities and no overlap.

So a number of physicists—particularly American ones—foresee a period when there will have to be increased international cooperation, even going so far as a transatlantic pooling of funds on projects such as, for example, the energy doubler at Fermilab. But according to the chairman of ECFA, Marcel Vivargent, this is impossible at present; CERN funds are very rigidly controlled by the member states and must be spent only for Europe. "But if LEP is accepted"

said Vivargent last week "we will have to discuss cooperation".

Leon Lederman, Fermilab director, raises an interesting issue: there are 26 European groups currently working at Fermilab, he says, who have come through the usual selection procedure by merit. "We have no way of assessing where a proposal comes from . . . but the energy doubler is going to raise a question of discrimination." With their (disputed) better funding the European groups will have better equipment for their experiments, he says, and without discrimination this would leave the Americans in the cold. There seems to be a possibility here that if competition does not ease, it will increase. No sharing of funds, no sharing of experiments, may be a new threat from the US to Europe.

Leon Van Hove, research director-general of CERN, feels that the normal exchange of groups (evidenced by the 26 European groups at Fermilab) will suffice; and that although exchange is increasing, no new procedure or institution (to match groups and laboratories) is necessary. The International Committee for the Future of Accelerators (ICFA) under the International Council of Scientific Unions (ICSU) would be sufficient to discuss the matter, he feels.

Burton Richter, on the other hand, believes that the old ways will not suffice, because of the large and increasing cost of the apparatus that must be built up around an accelerator to do a particular experiment. A single detector at LEP would cost about \$20 million, he estimates; who is going to pay for the apparatus, the group or the laboratory?

And how should the operating costs of the accelerators be divided? According to Lederman, Fermilab's electricity bill is presently \$7 million, and may rise to \$10-12 million next year (though the superconducting energy doubler, used not to double beam energy but to save accelerator power, could cut the costs 70%). And LEP, according to some estimates, if it used conventional magnets, could consume 500 MW of electrical power. (But that estimate is sensitive to the assumed radius, and to the energy of the machine. The consumption rises as the fourth power of the beam energy.) With costs and consumptions such as these, intercontinental cost-sharing may be necessary.

Whatever agreements may prove to be necessary on this level, there is a definite feeling both in Europe and the US that Europe now has the initiative. In the short term the US has PEP, which will be competitive with PETRA; in the long term, the American future depends on the

technology of superconducting magnets, which Fermilab is still wrestling with. (Another US machine for the mid-80s, Isabelle, a high energy East Coast machine to collide protons with protons, also needs superconducting magnets.) Lederman says Fermilab is about to go into a 1,000 magnet production run (they have produced 200 in various batches so far) but CERN cynics say they have heard that before; the technology is proving very difficult.

(If LEP needs superconducting accelerating cavities to save power costs and reduce that 500 MW to something manageable, it will face a problem of even greater magnitude. But test cavities are already in construction at Karlsruhe in West Germany for trials at DESY.)

Is there a simple reason why Europe appears to have taken the lead? According to Lederman, funding has a lot to do with it. "In the early 50s we were better funded, but somewhere in the 70s the budgets crossed." In CERN, it is not felt that Europe has much more money to spend—rather that the US is stretching its resources across too many projects. "If we had the energy doubler, PEP, and Isabelle, I wouldn't say we badly off" said one CERN physicist. And according to Leon Van Hove "to run three big labs on a small budget is trying to square the circle".

### Delayed advantage

Also, the delay in building the 500 GeV super proton synchrotron (the SPS) at CERN may, in retrospect, have been an advantage. While the US committed a large fraction of its funds to the construction of Isabelle, which many now see to be an outdated machine, it became clear that a major way forward in physics was to collide particles with their antiparticles (electrons with positrons, which gave us charm, or protons with antiprotons). Hence when the SPS was built, European physicists were free to use their new experience in allocating the potential European budget to the antiproton collider and to LEP.

Furthermore there appears to be a new mood in CERN. It used to be accused of being very strong on engineering—accelerator design—but unadventurous on physics. There was a strong division between the accelerator people who wanted a beautiful machine, and the users who wanted physics quickly. Now that divide is being bridged, and the accelerators are really being designed to suit the physicists, while the physicists are becoming more aware of the real constraints of design. LEP is certainly benefiting from this, and so is the antiproton collider.

That particular project is very instructive. An Italian with Italian temperament and American determination, Carlo Rubbia, who had been doing neutrino experiments at Fermilab and making a few discoveries (dimuons, events now connected with charm, and the anomaly later discounted at CERN), decided that the Fermilab and CERN accelerators could be used to make the intermediate vector boson (this latest holy grail of physics) if antiprotons could be injected into them the wrong way round. Simple in principle, but difficult in practice; but Rubbia was enough of an accelerator engineer to make some sensible proposals. He made them, to CERN and Fermilab, around 1976, and from then on the labs were in competition.

Then a number of interesting events occurred. First, it became clear that the vacuum in the Fermilab machine, at  $10^{-7}$  Torr, while good enough for the accelerator, would not do for day-long storage of intense beams (beams were lost in 30 minutes); while the SPS, over-designed to some American tastes at  $10^{-8}$  Torr and in easy reach of  $10^{-9}$  Torr, could do the job it had not been designed for.

Second, the CERN team in charge of future projects rejected the scheme, which involve creating antiprotons, catching them, and 'cooling' them into a confined beam, as impractical—so the project was taken on directly by people who were in favour of it. "There were people at CERN who were determined not to be beaten again" said one member of Rubbia's group. "They'd lost the J/psi and the upsilon to the US and they were not going to lose the IVB". There was, in fact, a kind of breakthrough by radical elements, greatly assisted by the persuasive powers of the antiproton advocate, Carlo Rubbia.

Third, the CERN directorate swung wholeheartedly behind the scheme (in fact they had a choice between two radical proposals, one involving electrons; it's arguable which was best) and put a good deal of CERN money into it.

And finally, the CERN accelerator physicists and engineers moved rapidly in reaching the solution of a very difficult technical problem, and proving it in a beautiful experiment, the initial cooling experiment (ICE). The project drew on all available CERN expertise, but decisions were taken sequentially as step after step was proved. There are still two years and many problems to go, but the antiproton projects appears to be CERN at its very best—using not only its skills, but also a large dash of imagination. Yes, Professor Lederman, it's going to be a very difficult combination to beat. □

# Science in Bolivia: the great divide

Bolivia has had 190 Presidents in 150 years of independence. Seven out of 10 of its poverty-stricken people are illiterate, and yet the country has eight 'liberal' universities for the privileged few, generally those of European descent.

This frustrating formula is carried over into science: research is confused, geared to foreign backers and largely unrelated to the needs of the people.

**John Hutton**, from the Department of Clinical Biochemistry at Addenbrooke's Hospital, Cambridge, visited Bolivia on a Nature writing fellowship.

THE village of Patacamaya lies to one side of the road that links the commercial centre of Bolivia, La Paz, with the mining town of Oruro. To the outsider, it is just like any other of the windswept settlements scattered across the Altiplano, the high plateau where 60% of Bolivia's five million people live. The village square seems deserted, the adobe huts practically uninhabited. There is a pervasive air of forlornness, only dispelled when the first light appears on a Saturday. Before dawn, trucks that have arrived from all over the countryside crowd into the marketplace, stacked with produce and people. Salt blocks conveyed by llama trains from the salars to the south west are exchanged for fresh fruit and vegetables transported across the mountains from the jungle regions to the east. What money changes hands is spent on a few manufactured goods from La Paz or a farming implement forged in the open air foundry beneath the eyes of the crowd. In the late morning it is time to celebrate the purchase of a cow, perhaps, or consult with a herbalist, but by the afternoon the dust has settled and the stillness has returned.

Less than seven kilometres from the village, and in stark contrast, is a Ministry of Agriculture research station, a monument to the agricultural potential of the high plateau. Established on what was formerly an estate thought too poor for redistribution under the agrarian reform of 1953, it demonstrates the transformation that can be wrought by the application of machinery, fertilisers, and plant and animal breeding techniques. To the Indian farmer tracing a furrow behind a single-bladed wooden plough tethered to a pair of oxen or to the shepherd following his few llamas and sheep as

they seek sustenance amid the stones and stubble nearby, the research station seems no more of his world than is the Russian satellite tracking station also located at Patacamaya. If anything, it only serves to remind him that he stands outside the money economy, that nobody cares for his education, that some of his children will die before reaching adulthood and that none of his family can expect to live for more than fifty years. Although the revolution has given the native farmer back his land, it seems that the administration has no place for him. With respect to health and education, the rural dweller is ignored, left to eke out a subsistence living from an inhospitable environment with little but his own meagre resources.

Somewhere between the agronomist of the research station and the subsistence farmer there is another man: a farmer's son, perhaps, whose primary education at the local school sets him apart, and who sees no future for himself in the bleak countryside. Given the opportunity, he would make the journey to La Paz, in the hope of becoming a gardener or a servant, or to work in one of the few factories. In time he might hope to own a truck or to rent a stall in the sprawling marketplace, and his dreams would be to change his traditional habits, purchase a few goods such as a radio or television and to educate his children into a better place in society.

The present Bolivian educational system, which leaves 70% of the population illiterate, still finds a place for eight universities—despite the country's small population. Amongst them is the oldest university on the South American mainland, the Royal and Pontifical Higher University of San Francisco Xavier of Chuquisaca. Traditionally, these institutions served to maintain the Hispanic cultural heritage and they were dedicated to the

formation of a liberal professional elite, whose ranks excluded both women and the native population.

Today, amalgamated under the title of the Bolivian University, they are nominally non-sectarian, academically autonomous and open to all. Despite this, membership has generally remained the privilege of an urban class of European or mixed European extraction. Enrolments in economics, law, medicine and engineering still account for more than half the student population, and so the country has too many doctors and too many planners who, in the absence of appropriate jobs at home, are forced to seek employment overseas.

The pursuit of science, as a career leading to technical expertise or as a research discipline, is invested with little of the prestige attached to the liberal professions. University teaching is hampered by the national political instability which, combined with the volatility of the student population, can result in the suspension of classes at any time for periods of several months. The majority of teachers have little more than a basic degree or may even be unqualified, having obtained their position through personal influence. Even those with full-time positions often work at a second job, leaving their classes to one of their assistants, usually a final year student. In science, practical training is limited as there are often no laboratory facilities, or materials are restricted to what the student can provide from his own funds. Postgraduate education does not exist at present, but even if the plans for it were implemented, who would be the teachers? In short, the few students who wish to become scientists have little choice but to seek their training overseas.

Upon their return they may find limited opportunity for research except in the fields of cosmic ray physics or

*Drawings by Professor P. J. Schofield of the University of New South Wales, Australia*

high altitude physiology. Bolivia's geographical position, with a range of altitudes up to 7,000 metres above sea level and a large proportion of the population living at around 4,000 metres, provides an ideal laboratory for this type of research and has attracted investment from overseas in establishing research facilities in these areas.

Yet even here an overseas-trained scientist does not always find himself in a hospitable environment. His newly won diplomas may not be recognised, he may find difficulty in getting on to the university payroll and he will inevitably encounter pressure from his peers to conform to the sedentary existence of preparing reports or feasibility studies rather than hazard the difficulties of performing a concrete task. While his knowledge of his discipline may be superior to that of his colleagues, his adroitness and experience in the political realm may not match their skills. If this is the case, he may be lost. The few scientists who do succeed in establishing themselves in a productive research career do not always remain there. Summary dismissal for political reasons may terminate their work, or, by a more insidious process, they may find their efforts spread over too many projects, and their energies dissipated by travel overseas to consult upon the development of their country.

A better climate for science seemed in store at the end of 1977, when President Banzer established by supreme decree a Council of Science and Technology with the powers to

assess and direct scientific research within the country. This was the first time that any Bolivian government had recognised that current research could be of use, and that further investment in research might assist in the development of the country. The council has not, however, received a great deal of financial support, and it may be only a gesture in response to pressure from the Organisation of American States and the United Nations. Nevertheless, despite two changes in the military government and the usual administrative reshuffling that accompanied these, it manages to survive and is now making its plans known.

The scheme of development which is envisaged in the council's early reports is implicitly that of the construction of a Western-styled, capital-based, consumer society. Progress towards this is to be achieved by the further exploitation of mineral resources, the production of cash crops for the export market and the expansion of industry with the aid of foreign technology. The scientist is seen as the source of new technologies which will help relieve the stranglehold imposed by foreign corporations. The council sees the promotion and funding of local research, however, as the responsibility of industry, or of the developed world through the establishment of an international fund. But what investor is going to be so benevolent as to buy his way deliberately out of a market? Institutions such as the International Development Bank, after all, do not invest their money for love.

In keeping with the council's broadly defined goals, steps have been taken through the universities and their associated institutions to support on-going research which has the potential for immediate economic impact, and to encourage specific projects of an applied nature. Such changes are to be made within the framework of the present budgetary restraints, a move which seems to lead inevitably to the demise of cosmic ray physics and high altitude physiology. On the other hand, the futility of supporting too many specific projects is revealed by a glance at any of the laboratories throughout the country, many of which house elaborate equipment that has never been operated or even installed. The situation is invariable: the initial project grant failed to account for the services of a skilled technician, a part was missing or an essential chemical not ordered, and by the time funds were available again and the deficiencies made good, time had passed, enthusiasm waned and the research team disbanded.

The agricultural research station at Patacamaya is one project which has fulfilled its aims. But the agronomists who are bent on emulating an agricultural system designed to suit another physical and economic environment often find it difficult to see past the superstition and ignorance that surrounds them. Even if they attempted to make contact with their neighbours, the chances are that there would not be a common language in which to communicate their ideas. The agro-

Farm tools for sale in La Paz market

"A pervasive air of forlornness . . ."—pictures by John Hutton

nomist may speak only Spanish, the sole idiom in which education is available, while the native farmer may speak only Aymara, the native tongue of the high plateau. Disillusionment is mutual. The frustrated scientist may well question the validity of sophisticated techniques such as ova transplantation or investigation into animal genetics when there seems to be little scope for the implementation of this kind of technology. No wonder that his sharper colleagues have taken office jobs in La Paz or that almost half the class with whom he graduated have left Bolivia permanently.

The experience of other Latin American countries suggests that investment into applied research only is in fact a costly and inefficient path to the development of new technologies. It is important for these countries to

encourage basic research, develop teaching standards and invest in library facilities: in sum, to construct the base of an indigenous establishment which could eventually define and resolve scientific problems within the context of the society.

In a country which has seen more than 190 presidents in the 150 years since colonial rule ended, and where government is largely a question of survival, a change of heart is essential if a longer view of investment in scientific research is to be propagated. Meanwhile, Bolivia has few safeguards against the encroachment of modernity and almost no inherent means of curbing the aspirations of a ruthless dictator or foreign investor. Given the present state of the society, it seems that Bolivian science and technology will remain the artefacts of the more developed powers. One wonders, then, how much longer will the agronomist and the native farmer, each surrounded by the trappings of his own culture, continue to gaze uncomprehendingly at each other's flocks across the fence? □

## Double standards

TWENTY years ago in Britain there was considerable concern that pesticides might wipe out much of our wildlife. Thousands of corpses of seed eating birds were found in the cornfields of East Anglia, poisoned by aldrin or dieldrin, used as a seed dressing to protect the newly-planted grain from attack by the wheat bulb fly. Hawks which preyed on these seed eaters, and foxes and badgers which ate their corpses, were also affected, and the population of the Peregrine falcon was eliminated from many parts of the country. When the cause of this holocaust was recognised, British farmers and pesticide manufacturers agreed in 1962 to a voluntary ban on the more dangerous use of these pesticides, and since then the situation has greatly improved. The slaughter of seed eating birds has ceased, and the populations of predators have increased considerably. There are still isolated incidents when pesticides kill numbers of birds and other animals, usually arising from the misuse of the chemicals, but in general the situation is satisfactory.

This improvement in Britain occurred as a result of the cooperation of naturalists, scientists and industry. Bodies like the voluntary organisations of ornithologists, the Royal Society for the Protection of Birds and the British Trust for Ornithology, worked closely with the government supported Nature Conservancy and the official Ministry of Agriculture to spell out the recommendations of the Pesticides Safety Protection scheme with the members of the chemical industry. It is perhaps significant that their successful regulations were brought into force some time before the appearance of Rachel Carson's book, *Silent Spring*, which is often thought to have alerted people to the danger of pesticides. Scientists had been well aware of the dangers for several years, and, as I have indicated, had done something practical about them. I fear that the main effect of *Silent Spring* was to make the uninformed over-react, and to deny the safe use of beneficial chemicals to many people throughout the world.

However, the situation varies from country to country. It has often been alleged that while the chemical industry has been very responsible in developed countries like Britain and other parts of Western Europe, where they have restricted their sales of chemicals known to endanger wildlife and the environment, they have behaved quite differently overseas. Up

KENNETH MELLANBY

till now I have seen little evidence that they are dumping chemicals abroad that they cannot sell in western countries. However, recently on the shores of Lake Titicaca, 3,812 m above sea level in the Peruvian Andes, I saw a huge, ugly hoarding advertising aldrin on behalf of the Shell company. Quite apart from the visual pollution of a beautiful previously quite unspoiled landscape, I doubt the wisdom of this commercial enterprise. I also saw, in the offices of the government agricultural officer at Junin, only a few kilometres from the even higher Lake Junin (4,081 m), a pictorial calendar advocating the use of a whole battery of organochlorine pesticides the use of which is strictly controlled or even banned in most developed countries.

I would be the first to agree that medical and dietary problems in developing countries are such that pesticides are essential, and that to save human lives wildlife may sometimes have to be put at risk. With skilled operatives, there may be a place in Peru for aldrin. But all countries, developed and developing, need a code of practice something like that so well observed by industry in Britain. If substantial amounts of aldrin get into the hands of the unsophisticated peasant farmers of the high Andes, the chemical is bound to find its way into the lakes and rivers. There it could well be concentrated in the bodies of the fish and other aquatic life, and could then be passed along the food chain to the unique birdlife of the region. The result could be an ecological disaster. The economic gains to the chemical industry or to the farmers are surely not sufficient to justify such risks.

## Why do messengers wear caps?

from M. J. Clemens

DURING the past decade we have learned a great deal about the structures of messenger RNA molecules in both bacterial and higher cells. Pains-taking work in several laboratories has brought molecular biologists from a position of doubting whether such entities really existed to one of considering which particular structural features enable these molecules to function as the efficient carriers of genetic information in living cells. One of the most exciting (and unexpected) developments in this story was the discovery of the 'cap' structures at the 5' ends of most eukaryotic (but not bacterial) mRNAs. These caps comprise a methylated guanosine residue linked by a 5'-5' triphosphate group to the first coded nucleotide of the RNA; the latter, and the subsequent nucleotide in the sequence, can also be methylated, giving rise to structures of the type  $m^7G(5')ppp(5')X^m pY^m$ .

There is now a considerable amount of information concerning the biosynthesis and the functions of cap structures in eukaryotic cell and viral mRNAs (reviewed by Shatkin *Cell* **9**, 645; 1976 and more recently by Filipowicz *FEBS Lett.* **96**, 1; 1978). Several possible roles for caps have been proposed, including stabilisation of mRNAs against degradation by 5'-exoribonucleases. Greatest attention, however, has been paid to the influence of the structures on the efficiencies of translation of mRNAs. Several complementary studies, which have included the use of uncapped and capped molecules as templates for cell-free protein synthesis, and investigation of the effects of compounds which resemble the cap structures, have revealed that the presence of a cap usually enhances the ability of a messenger to code for a polypeptide chain. In the cases where the mechanism of this enhancement has been investigated, it appears that capped mRNAs bind to ribosomes more rapidly and to a greater extent than their uncapped counterparts.

This important observation has raised the additional question of how

those mRNAs that are not normally capped function as templates for protein synthesis; in particular, how do bacterial messengers cope with this problem and what would be the effects of introducing caps on to these molecules? Some of the answers to these questions are supplied by two papers by Paterson and Rosenberg in this issue of *Nature* (page 692). They have found that several prokaryotic mRNAs can be translated quite efficiently in a cell-free system derived from wheat germ provided that the 5' ends of these messengers are modified by addition of a methylated cap structure. This modification was achieved in two ways, either using the endogenous capping activity of the wheat germ system with S-adenosyl methionine as methyl donor, or using enzymes purified from vaccinia virus to add the cap and then re-extracting the RNA before adding it to the cell-free system. By such manipulations the efficiency of translation of defined mRNAs of bacteriophage  $\lambda$  and of the *E. coli* gal mRNA could be made comparable with that of the eukaryotic globin mRNA.

These results must indicate considerable evolutionary conservation of the mechanism by which the protein synthetic machinery recognises its templates; apart from the absence of a cap the normal structural features of bacterial mRNAs appear to be sufficient to permit their utilisation by the wheat-germ extract. But how do bacterial ribosomes bind to uncapped bacterial mRNAs? Clearly there must be different structural features of the latter which facilitate such interactions. One such feature is the presence of nucleotides on the 5' side of the initiating AUG codon which can form base pairs with sequences at the 3' end of 16S ribosomal RNA (Shine and Dalgarno *Proc. natn. Acad. Sci. U.S.A.* **71**, 1342; 1974). It is interesting that eukaryotic mRNAs, in contrast, generally cannot form extensively base-paired complexes with eukaryotic 18S rRNA and, as pointed out by Rosenberg and Paterson, neither can

the mRNAs they have used. One reason for the appearance of cap structures in higher cells may therefore be to replace the direct mRNA-rRNA interaction which facilitates ribosome binding in prokaryotic organisms. Because cap structures appear not to bind to ribosomes directly, but require one or more additional protein initiation factors for this process, we may also have a partial explanation for the greater number of such factors needed for successful eukaryotic protein synthesis, relative to the prokaryotic process.

We are now in a position to see in outline how eukaryotic cell ribosomes may find the AUG initiation codons on mRNAs, according to the model recently proposed by Kozak (*Cell* **15**, 1109; 1978). Native small ribosomal subunits carrying initiator methionyl-tRNA bind at or near the 5' cap structure and then move along the RNA, scanning its sequence until an AUG is soon encountered, which will be complementary to the anti-codon on the tRNA. The large ribosomal subunit then attaches and protein synthesis can commence. Thus, polypeptide assembly begins at the first AUG codon occurring at the 5' end of the RNA. A prediction from this model is that internal AUG triplets are not used as initiation sites and that eukaryotic ribosomes cannot translate cistrons other than the 5'-proximal one in polycistronic mRNAs, even after cap addition. This prediction is borne out by the results described by Rosenberg and Paterson, making it tempting to suggest that cap-dependent initiation is the reason for the absence of functional polycistronic mRNAs from higher cells.

In addition to the mechanistic implications of these experiments, some practical considerations arise concerning the efficient expression of foreign

M. J. Clemens is in the Department of Biochemistry, St George's Hospital Medical School, London.

genes in both animal and bacterial cells. The addition to prokaryotic mRNAs of cap structures, with or without the non-coding sequences adjacent to them, by means of chemical, enzymatic or genetic engineering

techniques, could amplify the synthesis of certain bacterial gene products in higher cells (assuming the RNA can be introduced successfully into the cells). Conversely, there may not be a need for 5' caps on eukaryotic mRNAs

which are to be translated within bacterial cells. Other structural features of the molecules, including their potential ability to base pair with 16S rRNA and to be recognised by bacterial factors, may be more important. □

## Processing of protein precursors

from D. F. Steiner

WORK with a wide variety of secretory proteins has by now amply substantiated the 'signal hypothesis'. Proteins that are eventually going to be secreted are synthesised on ribosomes attached to the endoplasmic reticulum (ER) and transferred into the lumen of the ER from where they are finally released from the cell. The signal hypothesis states that these proteins initially contain an N-terminal 'signal' region which during translation guides the attachment of the ribosomes to the ER. The signal sequence is cleaved off shortly after the protein is segregated into the cisternae of the ER prior to secretion.\*

One difficult exception to the signal hypothesis has been ovalbumin, which is secreted into the ER and glycosylated without the apparent participation of a cleaved signal sequence. However, the laboratories of both R. Palmiter (University of Washington, Seattle) and G. Blobel (*J. Cell. Biol.* **79**, 567; 1978) have found that ovalbumin competes with other presecretory proteins for transfer into microsomes in reconstituted translational systems, implying the presence of a functional leader sequence. This apparent paradox has now been resolved by a dramatic announcement by V. Lingappa *et al.* from Blobel's group (Rockefeller University) that a prepeptide-like 'signal equivalent' sequence can be released from ovalbumin by tryptic digestion and that this sequence is located more than 200 residues into the molecule. This region contains all the competing activity, and from its position and composition can be inferred to contain a modified version of the typical N-terminal presequences of several other oviduct presecretory proteins (studied by Palmiter's group). It is not yet known whether this region functions as a signal peptide in the transfer of ovalbumin across the ER membrane,

and if it does, how the very long N-terminal region of the nascent chain could be transferred.

However, the finding of an apparent signal sequence at an internal site rather than at the N-terminal end itself, lends support to the 'loop' models of protein transfer into the ER, as against the membrane pore model, originally put forward by Blobel and Dobberstein, in which it was postulated that proteins are threaded through membranes, N-termini first. The loop models proposed by Inouye (*A. Rev. Biochem.* **47**, 481; 1978) and by Steiner *et al.* (*Proc. int. Symp. Proinsulin, Insulin and C-peptide*, 1978, Elsevier, in the press) suggest that the lipophilic signal sequence interacts with the membrane and assumes an inverted transmembrane orientation. Steiner and colleagues at the meeting suggested that the 9-10-residue region of the signal sequences interacts with components spanning the membrane and that successive formation of hydrogen bonds within the apolar membrane core between the pre-existing and the entering prepeptide strands produces a peptide loop across the membrane. Such a receptor mechanism could depend more on secondary than on primary structure and could explain the apparent lack of specificity in the binding of the various presequences. The loop mechanism is supported by preliminary evidence from P. Quinn *et al.* (University of Chicago) that the N-terminal region of the lead peptides of rat growth hormone and human placental lactogen (HPL) remain outside vesicles in *in vitro* transfer experiments and are released into the medium as small residual peptides.

As G. Scheele (Rockefeller University) pointed out in discussion, the loop model may provide a mechanism for incorporating multiply inserted proteins into membranes. It also seems possible that it might provide a means for inserting transmembrane proteins with 'inverted' N → C polarity across the membrane.

### Converting enzymes

Protein processing is not confined to the cleavage of signal sequences, however. Most polypeptide hormones, for example, are synthesised as much longer 'prohormones' which are subsequently processed to produce the biologically active product. The nature of the trypsin-like and carboxypeptidase B-like enzymes responsible for the cleavage of the paired basic residues (which mark the cleavage sites) in many of the prohormones remains unclear. The cleavage of nerve growth factor and epidermal growth factor (discussed by E. Shooter, Stanford University) is carried out by specific trypsin-like peptidases which form one of the subunits of the high molecular weight complexes in which these growth factors occur. The complexes thus seem to resemble proteinase/inhibitor complexes.

The signal peptidase activity in detergent-treated microsomes has been partially characterised. There is now general agreement that it is a neutral endopeptidase latent within untreated microsomes and is probably associated with the luminal face of the microsomal membrane. Its inhibition by high concentrations of 1,10-phenanthroline and several thermolysin inhibitors (M. Zimmerman *et al.* Merck, Sharpe and Dohme, Rahway, New Jersey) suggest that it may be a metalloprotease.

An interesting viral cleavage system is that of Sindbis virus. In this case a multicistronic mRNA encodes the capsid protein followed, without punctuation, by the two virus glycoproteins which become membrane-associated. Schlesinger *et al.* (Washington University, St Louis) have shown that the nascent polypeptide itself cleaves off the N-terminal capsid portion autocatalytically before tandem translation of the glycoproteins which are then vectorially coupled to fatty acids within the membrane and cleaved

\*A conference on Precursor Processing in the Biosynthesis of Proteins was held in New York City on 2-4 May, sponsored by the New York Academy of Sciences. It was organised by D. F. Steiner and M. Zimmerman.

D. F. Steiner is Professor of Biochemistry at the University of Chicago.

to their mature peptide forms. The tandem arrangement of these proteins suggests again the possibility that a functional signal sequence need not be at the N-terminus of a nascent polypeptide.

### Genetics

The advent of recombinant DNA techniques has greatly facilitated studies of the structure of the genes coding for protein precursors. Most remarkable at the meeting was the wealth of information gained from structural studies at the nucleotide level by Howard Goodman and coworkers on cloned mRNAs for rat and human growth hormones and the related peptide human chorionic sommatomammotropin (HCS). Studies of the corresponding chromosomal genes of HGH and HCS indicate the presence of multiple intervening sequences, while the gene for rat insulin I from the hooded rat was found to contain only a short intervening sequence in the 5' untranslated portion of the gene. Further studies on cloned rat preproinsulin genes derived from a Wistar-related strain, reported by P. Lomedico *et al.* from W. Gilbert's laboratory (Harvard University) confirmed the presence of a single intron (of 119 bp) upstream from the initiation codon in the gene for rat preproinsulin I, while the gene coding for preproinsulin II contained an additional intron of about 500 nucleotides between the region encoding amino acids 38 and 39 of the proinsulin II peptide chain (thus being in the C-peptide region). Their finding of nuclear RNA molecules larger than preproinsulin mRNA, confirming an earlier report by Duguid *et al.* (*Proc. natn. Acad. Sci. U.S.A.* **75**, 3249; 1978) indicates that the intervening sequences are transcribed into precursor mRNAs. Similarly in studies on growth hormone biosynthesis in rat pituitary GH cells pulse-labelled with uridine F. C. Bancroft *et al.* (Sloan-Kettering Institute, New York) have identified a nuclear 20S mRNA precursor which is slowly processed to the mature 12S mRNA of the hormone.

N-terminal partial sequence studies of the pro-opiocortin precursor of the cell-free translation product of its mRNA by E. Herbert *et al.* (University of Oregon, Eugene), and by N. G. Seideh *et al.* from M. Chretien's laboratory (McGill University), have confirmed the presence of a signal sequence predicted from the recently completed nucleotide sequence of the DNA (Nakinishi *et al.* *Nature* **278**, 423; 1979). They have also established the presence of a cleavage site between Gly-Trp, 26 residues in from the initiator codon. R. Mains and B. Eipper (University of Colorado, Denver) presented recent studies showing that one of the pro-opiocortin precursors (31K) is processed

differently in pars intermedia than in the anterior pituitary, favouring production of  $\alpha$  melanocyte stimulating hormone in the former and of adrenocorticotrophic hormone in the latter tissue. The basis for this difference in processing in the two tissues is unknown.

An exciting new approach to studies at the nucleotide level of less abundant mRNA species came from the demonstration by K. Agarwal *et al.* (University of Chicago) that synthetic nucleotide primers can be utilised to detect and selectively transcribe into cDNA those mRNAs which are present below the 1% level in poly A-containing RNA fractions from tissues. Application of this approach to studies on gastrin mRNA mixtures led to the successful identification of a 620-nucleotide mRNA coding for gastrin G34 and indicated the presence of additional amino acid sequences on both sides of the G34 coding region (*Proc. natn. Acad. Sci. U.S.A.* **76**, 1770; 1979). These results predict that progastrin is 110–140 amino acids long and provide the necessary means to purify and ultimately clone the mRNA for this hitherto unexplored precursor molecule. This method is obviously of wider applicability and will undoubtedly provide a new strategy for identifying and amplifying important gene and mRNA structures.  $\square$

## Is unification really true?

from Norman Dombey

THERE is a general consensus in the world of elementary particle physics that electromagnetic interactions and weak interactions (responsible for nuclear  $\beta$ -decay) are just different aspects of the same theory (*News and Views* **278**, 209; 1979). The predictions of the standard unified gauge theory of weak and electromagnetic interactions based on the group  $SU(2) \times U(1)$  have been verified in every high energy scattering experiment so far performed, culminating in the remarkable demonstration of parity violation at Stanford last year when a difference was observed in the scattering of left-handed electrons and right-handed electrons off a deuterium target (*News and Views* **274**, 11; 1978). Indeed the July/August issue of the *CERN Courier* then remarked that the only remaining problem in the field was to find a suitable name for the unified theory.

A note of caution was sounded recently by Barut (*Nature* **278**, 692; 1979) who noted that the crucial test for a unified theory was the observation of the spectrum of gauge particles or quanta of the theory

with masses of the scale  $e/G^{\frac{1}{2}} \sim 90$  GeV where  $e$  is the electric charge and  $G$  is the Fermi constant of the weak interactions. The combination of the two basic coupling constants in this way would be the decisive feature of a unified theory.

I shall attempt here to take this comment further and to review critically the present evidence for unification. I will indicate in fact that the successes of the standard theory could be the result of the inclusion in that theory of assumptions which have nothing to do with the unification of weak and electromagnetic interactions.

The experiment situation as far as high energy scattering is concerned can be summarised thus: all neutrino neutral current experiments with nucleon targets whether inclusive (that is of the form  $\nu N \rightarrow \nu X$  where  $X$  is unobserved) or exclusive (for example,  $\nu N \rightarrow \nu N$ ,  $\nu N \rightarrow \nu N \pi$ ) together with the Stanford polarised electron experiment are consistent with a neutral weak current of the form written down by Glashow (*Nucl. Phys.* **22**, 579) in 1961 in his pioneering attempt to unify weak and electromagnetic interactions through the group  $SU(2) \times U(1)$ . This current is

$$J_{\mu}^w = V_{\mu}^3 + A_{\mu}^3 - 2\sin^2\theta J_{\mu}^{\text{em}} \quad (1)$$

where  $V_{\mu}^3$  and  $A_{\mu}^3$  are the neutral isospin components of the vector and axial currents whose charged components constitute the current of the normal  $V-A$  theory of  $\beta$ -decay, and  $J_{\mu}^{\text{em}}$  is the electromagnetic current. Experimentally  $\sin^2\theta = 0.24 \pm 0.02$  (*Proceedings of Neutrino 78*, 253, Purdue University Press, 1979).

Glashow, however, was unable to predict the strength of neutral current scattering by neutrinos compared with charged current scattering (that is  $\bar{\nu} + N \rightarrow \mu^-(\mu^+) + X$ ) because he did not know the relation between the mass  $M_Z$  of the neutral gauge particle  $Z^0$  of his theory compared with the mass  $M_W$  of the charged gauge particles  $W^{\pm}$ . The strength of charged current scattering is given by the Fermi constant  $G$  where  $G/\sqrt{2} = g^2/8M_W^2$  as a  $W^+$  or  $W^-$  is exchanged in the process ( $g = e\sin\theta$  is the weak coupling constant). For scattering by neutral currents the appropriate Fermi constant  $G'$  is given in  $SU(2) \times U(1)$  by  $G'/\sqrt{2} = g^2/16M_Z^2\cos^2\theta$  as now a  $Z^0$  is exchanged.

This problem was solved by Weinberg (*Phys. Rev. Lett.* **19**, 1264) in 1967 by using the Higgs mechanism of spontaneous symmetry breaking to generate the masses  $M_W$ ,  $M_Z$  thereby finding that  $M_W = M_Z\cos\theta$ . Hence the relation between  $G'$  and  $G$  in the standard theory is just

$$G' = \frac{1}{2}G \quad (2)$$

The best value for the neutral current

strength in neutrino scattering is conveniently written in terms of  $\kappa = M_Z \cos \theta / M_W$ . Then  $\kappa^2 = 0.98 \pm 0.05$  (*Proc. Neutrino 78*, 253) in close agreement with the Weinberg value  $\kappa = 1$ .

Thus the standard theory predicts with remarkable accuracy both the form and the strength of the weak neutral current in high energy scattering experiments. The only difficulty at present in the experimental verification of the theory lies in the conflicting results on atomic parity violation in bismuth (*Proc. Neutrino 78*, 417; *News and Views* 264, 505; 1976) and thallium (*Phys. Rev. Lett.* 42, 343; 1979): the Washington experiment which has the smallest reported errors disagrees by some seven standard deviations from the predictions of the standard theory. These experiments, however, are very difficult and require for their interpretation a model of heavy atoms of uncertain validity.

Hence the general consensus that the standard theory has been verified. The sceptic must now remark that all the data so far observed are consistent with the old Fermi four-fermion theory of weak interactions, provided that neutral currents are included with the form (1) and strength (2). No additional structure in weak interactions due to the existence of gauge particles  $W^\pm$ ,  $Z^0$  with their prescribed masses of 78 and 90 GeV respectively has been observed, nor is there any experimental evidence yet for the scalar Higgs particle required by the theory. Neither (1) or (2) is especially complicated so there may well be a simple explanation of these two relations which does not require the untested features of the standard unified theory: in particular the predicted masses for  $W^\pm$  and  $Z^0$  and the existence of the Higgs scalar.

Hung and Sakurai (*Nucl. Phys.* B143, 81; 1978) did indeed find recently an extremely simple explanation of (1) and (2). They showed that starting with the isospin- or SU(2)-conserving V-A theory of weak interactions including neutral currents due to Bludman (*Nuovo Cimento* 9, 433) in 1958, then the  $W^0$  which couples to the neutral weak current and the photon  $\gamma$  which couples to the electric current must mix quantum mechanically. This is because both electrons and quarks can be left-handed (for the V-A weak coupling) and charged. If this calculation is done carefully, making sure that the photon is massless both before and after mixing, then not only is the Glashow current (1) obtained with  $\sin^2 \theta$  as a measure of the mixing—which it is in the standard theory anyway—but also the mixing does not change the relation  $G' = \frac{1}{2}G$  which comes simply from isospin invariance in

the underlying theory. Thus the two successful predictions of the standard theory are obtained from a mixing calculation with no extra assumptions about unification, gauge theories or Higgs particles. From this point of view all the successes of the standard unified gauge theory are just due to the correct incorporation of  $\gamma$ - $W^0$  mixing in the formalism.

Hung and Sakurai consider that their calculation is an alternative approach to weak and electromagnetic interactions that contains the standard theory and may but does not necessarily, give different results. They emphasise that from the mixing point of view,  $\sin^2 \theta$  should be

considered as a function of momentum transfer  $q$  and not as a fundamental constant, and that the electron and muon neutrinos would have different interactions with the electromagnetic field, and therefore different values of  $\sin^2 \theta$  should be associated with different neutrinos. Their motivation seems to be mainly a dislike of the Higgs particle which is a necessary ingredient of the standard theory but whose mass is arbitrary and is not predicted by the theory. The number of Higgs particles is also arbitrary but in the standard theory, the simplest choice of one Higgs is made, thereby obtaining relation (2).

Although Hung and Sakurai do not

### SOCIETIES AND ACADEMIES

BOSTON (U.S.A.)

**American Academy of Arts and Sciences**, May 14.—Hon. Charles Francis Adams in the chair.—Dr. H. P. Bowditch presented a new form of plethysmograph differing from those of Mosso and van Basch in the method adopted for securing a constant level of the fluid in the receptacle connected with the apparatus which contained the body whose changing volume was to be measured. The method consisted in suspending the receptacle (a large sized test tube) to a delicate spiral steel spring of which the length and strength were so adjusted that the weight of the fluid flowing into the test tube caused an elongation of the spring precisely equal to the rise of the fluid in the test tube itself. Thus the absolute level of the fluid in the receptacle remained unaltered, and a constant pressure was maintained upon the surface of the organ to be measured. An index attached to the lower end of the spring recorded upon a revolving cylinder covered with smoked paper the flow of the fluid into and out of the receptacle.—Mr. N. D. C. Hodges gave two new proofs of the dimensions of molecules, one based upon the properties of water and aqueous vapour, the other upon superficial tension and considerations of the depth of the superficial layer of molecules upon sheets of platinum.—Prof. Pickering exhibited a new form of photometer for measuring the light of a nebula or comet, by comparison with a star thrown out of focus. The method employed eliminated the effects of moonlight or twilight. He also proposed to denote the light of these bodies in stellar magnitudes. Thus a portion of a nebula would be of the twelfth magnitude, if of the same brightness as a twelfth-magnitude star spread over a circle one minute in diameter.

### Evolution Old and New

MR. A. R. WALLACE writes, in *NATURE*, vol. xx. p. 143, that, according to the theory which I support, Australian (and more especially Queensland) sheep should show a tendency to grow a scantier and thinner fleece than their English ancestors. "If Mr. Butler," he continues, "could adduce on good authority such a fact as this, he would have some evidence in his favour, instead of which he can only make suppositions."

I never was in Australia, but had some years' experience of sheep-farming in New Zealand. It was generally believed, in my time, that fleeces soon became short and hairy in Queensland, and even in the more northern part of New South Wales. You must, however, have many readers who could tell us what the facts are. May I hope that you will kindly insert this, so as to get the matter settled by eliciting information from a competent authority? I am speaking, of course, of sheep that are left to the effect of the climate, without being frequently crossed with rams from colder countries. Do the fleeces of such sheep deteriorate in Queensland? S. BUTLER

June 12

### Oxygenated Rain

ON Thursday, June 12, at half-past eleven in the morning, a remarkable shower of rain fell over London, which might almost be described as "effervescent;" the drops whilst falling appeared to be colourless and perfectly transparent, but on striking against any solid surface they became milky, and on close examination it was evident that this cloudy appearance was caused by a number of very minute air-bubbles, which rapidly increased in size, and then burst. From the bleaching power which this rain appeared to have, I am led to believe that there was nascent oxygen in the gas thus evolved. Those who traverse the streets of London in the early morning may now and then observe the red colour of all bright iron-work in the pavement, such as coal-plates, &c., due to the oxidising influence of a thunder-shower in the night; this effect does not follow every thunder-shower, but seems to indicate a peculiar atmospheric condition. Have any memoranda on this subject been recorded? EDWARD SOLLY

From *Nature* 20, 19 June, 169, 188; 1879.

Norman Dombey is in the Physics Division of the School of Mathematical and Physical Sciences, University of Sussex.

claim that a theory different to the standard theory results from their work, it is possible to envisage a radical alternative to the standard theory starting from  $\gamma$ - $W^0$  mixing. The motivation now is that if  $\sin^2\theta$  were essentially a radiative correction as these ideas suggest then  $\sin^2\theta \approx \alpha \approx 1/137$  whereas experimentally  $\sin^2\theta \approx 1/4$ . This means that the radiative corrections must be much larger than expected; yet they can only be much larger if higher order weak interactions are important. This implies that  $g^2/4\pi \gtrsim 1$  whereas in the unified theory  $g = e\sin\theta$  so  $g^2/4\pi < \alpha$ . Hence now  $M_W, M_Z \gtrsim 1/G^1 = 300$  GeV.

Of course the alternative approach is not a complete theory, it is just a calculation of quantum mixing which must be part of any theory. So if the radical alternative is taken seriously, it is necessary at some stage to consider what happens at high energies ( $\gtrsim 300$  GeV) where the four-fermion theory must break down. What does happen cannot yet be predicted but significant progress has been made recently on treating the four-fermion interaction as a serious theory in its own right by Cooper, Guralnik and their collaborators (*Ann. Phys.* **109**, 165; 1977; *Phys. Rev. Lett.* **40**, 1620; 1978; *Phys. Rev.* **D19**, 549, 562; 1979). The ideas here are based on the theory of superconductivity which of course also involves a four-fermion interaction, albeit one which is non-relativistic. The calculations are not performed perturbatively but in a mean field approximation as in many-body theory. Both vector (gauge) and scalar (Higgs) particles now appear as dynamical excitations of the theory, not as elementary entities, thereby removing the arbitrariness of the Higgs particle mass which many see as the most serious failing of the standard theory.

The theory of superconductivity may well provide a good analogy for weak interaction theory. Englert (International Centre for Theoretical Physics, Trieste, Report IC/76/92; 1976) has pointed out that the Higgs phenomenon has already been discovered experimentally, not in particle physics but in the Meissner effect. The range of penetration of the magnetic field is given by the photon mass induced by spontaneous symmetry breaking of the Ginsburg-Landau Lagrangian through the Higgs mechanism. Here the Higgs scalar can easily be understood: it is just the bound state Cooper pairing of the electrons of the BCS theory. The Ginsburg-Landau approach to superconductivity in terms of vector and scalar order parameters is the phenomenological theory, whereas the basic physics lies in the BCS four-fermion theory. In the same spirit, the standard unified theory could be regarded as a phenomenological theory of weak interactions valid in the region  $q^2 \ll M_W^2$ , or perhaps,  $m_e^2 \ll q^2 \ll M_W^2$  ( $m_e$  is the electron mass), while the four-fermion theory is funda-

mental. In a Los Alamos Report (LA-UR-79-306; 1979) I have noted that the latter possibility would allow  $\sin^2\theta \approx 0$  in atomic physics where  $q^2 \lesssim m_e^2$  thereby giving a value for atomic parity violation in bismuth or thallium about three times smaller than in the standard theory, a result which agrees with all the experiments performed to within 2.5 standard deviations.

If the radical alternative is correct, then two final remarks are appropriate. The first is theoretical. Weak interactions now become strong at energies of 300 GeV, they do not level off at a typical electromagnetic strength at 90 GeV or so. This provides a physical reason for a grand unification of leptons and hadrons at high energies which is missing from the usual viewpoint. The second remark is experimental. No  $Z^0$  will be seen at LEP for 70 GeV electrons on 70 GeV positrons. To ensure seeing some effects of weak interaction structure a centre of mass energy of at least 300 GeV is needed.  $\square$

## Oscillations in cellular reactions

by Eleanor Lawrence

A RECENT meeting\* in the Black Forest brought together some of those working in the field of cellular oscillating reactions. The periodic rise and fall in concentrations of metabolites or in membrane potential is found in a wide variety of cells. In some cases, such as the membrane potential changes in cardiac pacemaker cells, the physiological significance of the oscillating reaction is clear; in others the oscillatory phenomena may be a consequence of the underlying physico-chemical properties of the components of a particular reaction but may have no further physiological role. However, the general point was made at the meeting that an oscillating reaction provides a stable and energy-efficient signal whose modulation by metabolites, hormones or synaptic input could convey information rapidly and precisely to the cell itself or to its neighbours.

Some order, however arbitrary it

may eventually appear, can be imposed on this collection of diverse and seemingly unrelated phenomena by a division into 'cytoplasmic' oscillators on the one hand, of which the glycolytic oscillator is a prime example, and 'membrane' oscillators on the other. Self-contained models for oscillating membrane potential based on a cycle of inward and outward ionic currents are consistent with much of the experimental evidence. But whether membrane oscillators are in practice completely self-contained or whether they are in some cases driven by underlying internal oscillators is still an open question, and various possibilities were canvassed at the meeting.

### Glycolytic oscillator

Undoubtedly the cellular oscillator best characterised at the molecular level is the so-called glycolytic oscillator described by B. Hess (Max-Planck-Institut für Ernährungsphysiologie, Dortmund). Periodic regular oscillations in the concentrations of glycolytic intermediates were discovered first in yeast cells and later in extracts of skeletal muscle and heart. The key component producing the oscillations in this pathway is the allosteric enzyme phosphofructokinase (PFK), which catalyses the phosphorylation of fructose-6-phosphate into fructose-1,6-diphosphate using ATP as an energy source. The oscillations reflect the periodic changes in the activity of PFK (within a certain range of substrate input) in response to its activators F6P, ADP and AMP, and to its allosteric inhibitor ATP, which produces regular pulses of product to which the rest of the pathway is geared. The stability of the oscillations to the stochastic substrate input, expected normally, has been shown by experiments in which input was varied at random. In these conditions the reaction still oscillated at its 'normal' periodicity. Such oscillating reactions have the fascinating property of generating structure in initially homogeneous solutions, as Hess illustrated. When the reaction in a shallow unstirred yeast extract is followed by ultraviolet photography, which picks up the fluctuations in oxidised and reduced pyrimidine nucleotides, the solution soon takes on a regularly pulsing structure composed of discrete domains.

So far, however, evidence that the glycolytic oscillator could provide a basis for other oscillatory phenomena is sparse. R. Chaplain (University of Mainz) is accumulating evidence suggesting a link between glycolysis and the membrane potential oscillations represented by the periodic autonomous firing of certain neurosecretory neurones in the abdominal ganglion of the sea-hare *Aplysia*. I. Levitan and his

\*A meeting on 'Cellular Oscillators', organised by M. J. Berridge and P. E. Rapp, and sponsored by the Company of Biologists and Dr Karl Thomae GmbH, was held at Titisee on 22-24 March 1979. The proceedings will be published as Volume 81 of the *Journal of Experimental Biology* due out in August 1979.

colleagues (Friedrich-Miescher-Institut, Basel) with a different neurone in the same ganglion, find that oscillatory behaviour can be profoundly changed by changes in the internal concentrations of cyclic nucleotides. The inhibitory effects of synaptic stimulation can be mimicked by increases in cyclic AMP alone. The enhanced activity induced by vasopressin and oxytocin is simulated by increases in cyclic GMP and cyclic AMP together. These hormones naturally cause a rise in cyclic nucleotide levels. Levitan has also identified hormonal activity resembling that of vasopressin and oxytocin in peptide-containing extracts of molluscan ganglia.

#### Membrane oscillators

Detailed dissection of the ionic mechanisms of membrane potential oscillations reveals a slightly different picture in different tissues. However, in all cases the oscillatory behaviour appears to be due primarily to a slow outward  $K^+$  current which is normally responsible for membrane hyperpolarisation. As this current gradually inactivates it initiates membrane depolarisation leading into the upswing of the next action potential.

In cardiac pacemakers (the frog sinus venosus and the mammalian sinoatrial node) described by H. Brown and S. Noble (University of Oxford) and the Purkinje fibres described by R. Tsien (Yale University School of Medicine) the dominant pacemaking oscillation in membrane potential can be explained by a self-contained cycle of inward and outward currents which are activated and inactivated by the changes in voltage they produce. Brown and Noble together with D. DiFrancesco have been looking at the mechanism of the inhibition of pacemaking in the heart by acetylcholine and its acceleration by adrenaline. They find that acetylcholine in both mammals and amphibia greatly increases outward potassium current, possibly by opening up a special ACh-activated potassium channel. Adrenaline on the other hand, increases the slow inward  $Na^+/Ca^{2+}$  current and also affects a newly discovered additional pacemaking current, overriding the adrenaline-induced increase in outward current.

Although the dominant pacemaking membrane oscillations can be explained by a self-contained membrane model, as Tsien pointed out, pacemaker cells also probably contain a separate 'internal' oscillator largely independent of the main membrane oscillator, but which reveals itself in oscillatory changes in membrane conductance and cell contractility even when the mem-

brane potential is fixed. This internal oscillator is enhanced in conditions that raise internal free calcium, leading Tsien to suggest that the membrane conductance oscillations are driven by a cycle of uptake and release of Ca from some intracellular store, probably the sarcoplasmic reticulum. Increased intercellular free calcium is known to increase membrane permeability to  $K^+$ .

A cycle of Ca uptake and release, this time by the endoplasmic reticulum is invoked by P. G. Nelson (National Institutes of Health) to explain the oscillations in membrane potential seen in L cells subjected to mechanical or electrical stimuli. On electron microscopic evidence of specialised structures closely apposed to the membrane, Nelson proposes a model in which Ca-induced changes in membrane permeability to  $K^+$  are coupled to a cycle of Ca uptake and release from the ER. A similar  $Ca^{2+}$  cycle might also drive the periodic contractions in the veins of the acellular slime-mould *Physarum* (described by K. E. Wohlfarth-Bottermann, University of Bonn).

The role of calcium in controlling the frequency of bursts in the molluscan burster neurones was emphasised by R. W. Meech (ARC Unit of Invertebrate Chemistry and Physiology, Cambridge). He suggests that the prolonged inward current carried by  $Na^+$  and  $Ca^{2+}$ , which is responsible for the depolarising phase of the burst, is also responsible for a rise in intracellular Ca which then triggers the slowly developing outward  $K^+$  current responsible for the hyperpolarising interburst phase.

#### Link with glycolysis

A link with both glycolysis and cell Ca concentration is proposed by E. K. Matthews (University of Cambridge) for the membrane oscillations elicited in pancreatic islet cells stimulated to release insulin by glucose. The membrane oscillations themselves are again driven by changes in  $K^+$  conductance but in this case Matthews proposes a link with glycolysis. Glucose metabolism leads to a decreased permeability to  $K^+$  and so to depolarisation. The principal ion entering the cell during the bursts of action potentials superimposed on the crests of the membrane oscillation, is thought to be  $Ca^{2+}$ , which could also provide negative feedback, increasing  $K^+$  permeability and initiating the hyperpolarising interburst phase.

One organ in which the physiological role of cellular oscillations is clear although their mechanism is less clear, is the intestine. The smooth muscle in the wall of the stomach and intestine displays fairly slow oscillations in membrane potential—the 'slow wave'—which propagates along the intestine

(J. A. Connor, University of Illinois, Urbana). Contraction is initiated when action potentials are generated on the crest of the wave. In the cat at least, pacemaker activity seems to reside in the longitudinal layer of the musculature. Preliminary attempts to identify the primary oscillator point, in Connor's opinion, to rhythmic modulation of current from an electrogenic sodium-potassium pump, although other metabolic processes may be involved.

#### Chemical signals

Returning to 'metabolic' oscillators, one of the most spectacular is the aggregation of the amoebae of the cellular slime-mould *Dictyostelium* as a result of the propagation and amplification from cell to cell of a chemotactic signal carried by cyclic AMP. G. Gerisch (Biozentrum, Basel) speculated on possible metabolic control pathways leading to the periodic synthesis of cyclic AMP pulses. On the basis of strong evidence of oscillations in cyclic GMP activity, Gerisch has proposed a tentative scheme of feedback control loops in which cyclic AMP binding to the external receptor leads to an immediate rise in cyclic GMP which then activates adenylyl cyclase leading to increased cyclic AMP production. This in turn damps down the receptor-mediated increase in cyclic GMP. Gerisch sees the oscillations in adenylyl cyclase activity (possibly mediated by phosphorylation of the enzyme) as the primary oscillation in the pathway in contrast to other models which have taken the allosteric change in the receptor on binding cyclic AMP as the key component.

M. Israel (CNRS, Gif-sur-Yvette) described oscillations in the intracellular concentrations of ACh in *Torpedo* electroplax during stimulation. On the apparent fairly long-period rise and fall in intracellular ACh are imposed very short-period changes in ACh concentration which oscillate in phase with ATP concentration. As the amplitude of electrical discharge (reflecting transmitter release) does not oscillate, they conclude that transmitter output is not directly related to ACh concentration.

#### No unification

Summing up, M. Berridge (ARC Unit of Invertebrate Chemistry and Physiology, Cambridge) pointed the moral of the meeting—that there is no universal oscillator underlying the different phenomena described. Although the influence of calcium pervades many discussions of oscillatory mechanisms and Rapp and Berridge (*J. theor. Biol.* **66**, 497; 1977) have proposed the attractive notion that control loops involving calcium and cyclic nucleotides may be involved in many oscillating reactions, the existence of such controls remains to be demonstrated experimentally, and they are unlikely to be universal. □

## Coated pits, coated vesicles, and receptor-mediated endocytosis

Joseph L. Goldstein\*, Richard G. W. Anderson & Michael S. Brown

Departments of Molecular Genetics and Cell Biology, University of Texas Health Science Center at Dallas, 5323 Harry Hines Boulevard, Dallas, Texas 75235

*Proteins and peptides can enter cells by receptor-mediated endocytosis, a coupled process by which selected extracellular proteins or peptides are first bound to specific cell surface receptors and then rapidly internalised by the cell. Internalisation follows clustering of the receptors in specialised regions of the cell surface called coated pits that invaginate to form intracellular coated vesicles. It is now recognised that receptor-mediated endocytosis has a fundamental role in the growth, nutrition and differentiation of animal cells.*

CERTAIN proteins that bind to receptors on the surfaces of animal cells are rapidly internalised by the cells before they can dissociate from their receptors. This process, which is called receptor-mediated endocytosis, has recently become recognised as an important and general mechanism by which animal cells take up nutritional and regulatory proteins from extracellular fluid. Biologically important molecules known to be taken up by this mechanism include plasma transport proteins (such as low density lipoprotein and transcobalamin II), certain polypeptide hormones (such as insulin and epidermal growth factor), asialoglycoproteins, and lysosomal enzymes. In many cases, rapid internalisation of receptor-bound proteins is achieved by the clustering of receptors in specialised regions of the surface membrane called coated pits that invaginate rapidly into the cell during endocytosis to form coated vesicles<sup>1,2</sup>. Coated pits and coated vesicles have recently acquired the status of subcellular organelles because they can be separated from other cellular components and because they possess a characteristic structure and protein composition<sup>3,4</sup>.

We review here some of the experiments that have delineated the process of receptor-mediated endocytosis. We rely heavily on data gathered from extensive study of the low density lipoprotein (LDL) receptor system, which functions to transport cholesterol from plasma into cells<sup>5,6</sup>. We then review 12 other protein transport systems for which receptor-endocytosis has been documented. From such data, we deduce certain general features of the process that may apply in most types of animal cells.

### Receptor-mediated endocytosis as a mechanism for cellular protein uptake

Endocytosis is a general term that refers to the process by which cells ingest extracellular materials by trapping them within inward foldings of the plasma membrane that pinch off from the surface to form intracellular vesicles<sup>7</sup>. Endocytosis occurs widely in protozoa where it has an obvious nutritional role. In

multicellular organisms endocytosis was first identified in macrophages and other phagocytic cells that ingest foreign particulate materials and deliver them to lysosomes for degradation. With the advent of the electron microscope, it was recognised that endocytosis is not limited to phagocytic cells but occurs in all animal cells<sup>8</sup>. The rate of endocytosis in non-phagocytic cells can be appreciable. For example, mouse L cell fibroblasts internalise an amount of cell surface membrane equal to 50% of the cell surface every hour<sup>7</sup>. One reason for such rapid endocytosis now seems clear: it provides a mechanism by which cells take up necessary macromolecules from extracellular fluid in controlled conditions.

Within the past few years, at least 13 systems have been described in which non-phagocytic cells use endocytosis to internalise proteins that have become bound to surface receptors. These systems share four properties that collectively define receptor-mediated endocytosis: (1) The binding component on the cell surface is a receptor in the strict sense, that is, it is a molecule whose function is to bind an endogenous ligand and thereby achieve a physiological effect. This criterion distinguishes these receptors from other cell surface components that serve as binding sites for opportunistic foreign molecules, such as lectins and toxins, and viruses. (2) Internalisation of the ligand is effectively coupled to binding. Once the protein is bound to the receptor, the half-time for internalisation is less than 10 min<sup>9-18</sup>. (3) In all cases for which ultrastructural data are available, the receptor-bound proteins enter the cell through coated pits, either because the receptors spontaneously localise in these regions or because binding of the ligand induces migration of the receptors to coated pits<sup>2,19-24</sup>. (4) The internalised proteins are usually delivered to lysosomes where they are degraded completely to amino acids<sup>2,6,12-18,25,26</sup>; occasionally processing of the internalised protein involves delivery to cellular structures other than lysosomes (see below).

The LDL receptor system illustrates each of the four characteristics of receptor-mediated endocytosis. The similarities and differences between the LDL receptor pathway and other systems of receptor-mediated endocytosis are presented in Table 1 and discussed below.

**Table 1** Systems for receptor-mediated endocytosis of proteins

Protein	Cell type	Internalisation via coated pits and coated vesicles	Fate of internalised protein		Selected refs
			Degraded in lysosomes	Other	
<b>Transport proteins</b>					
LDL	Fibroblasts, smooth muscle cells, endothelial cells, adrenocortical cells, lymphocytes	Yes	Yes; cholesterol retained by cells	—	2, 6, 10, 52, 57
Yolk proteins (phosvitin, lipovitellin)	Oocytes (chicken, mosquito)	Yes	No	Delivered to yolk granules	21, 32
Transcobalamin II	Kidney cells, hepatocytes, fibroblasts	Data not available	Yes; vitamin B <sub>12</sub> retained by cells	—	14, 68, 69
Transferrin	Erythroblasts, reticulocytes	Yes	Data not available	Iron retained by cells	22, 60, 61
<b>Protein hormones</b>					
Epidermal growth factor	Fibroblasts, 3T3 cells	Yes	Yes	—	13, 23, 50
Nerve growth factor	Sympathetic ganglion cells	Data not available	Data not available	Carried in vesicles retro- grade up the axon	62
Insulin	Hepatocytes, hepatoma cells, lymphocytes, adipocytes, 3T3 cells	Data not available	Yes	Also delivered to Golgi apparatus and nuclei	12, 25, 50, 63, 64
Chorionic gonado- tropin	Leydig tumour cells, ovarian luteal cells	Data not available	Yes	—	15, 70
$\beta$ -Melanotropin	Melanoma cells	Data not available	Data not available	Delivered to Golgi apparatus and melanosomes	71, 72
<b>Other proteins</b>					
Asialoglycoproteins	Hepatocytes	Data not available	Yes	—	16, 17
Lysosomal enzymes	Fibroblasts	Data not available	No	Delivered to lysosomes and Golgi-associated structures; enzymes remain active for many days	65–67
$\alpha$ -2-Macroglobulin	Fibroblasts, macrophages, 3T3 cells	Yes	Yes	—	18, 24, 58
Maternal immunoglobulins (IgG)	Fetal yolk sac, neonatal intestinal epithelial cells	Yes	No	Transferred intact in coated vesicles to basal surface of cells where IgG is discharged into fetal or neonatal circula- tion	21, 47–49

## LDL receptor pathway as prototype for receptor-mediated endocytosis

Animal cells acquire cholesterol for synthesis of cell membranes by the receptor-mediated endocytosis of the cholesterol-carrying lipoprotein LDL, a large spherical particle (220 Å in diameter  $M_r \sim 3 \times 10^6$ ) that originates in the liver and circulates in the blood. Each LDL particle contains a nonpolar core composed of approximately 1,500 cholesterol molecules that are esterified to long-chain fatty acids. This cholesteryl ester core is surrounded by a polar coat of phospholipid, unesterified cholesterol, and protein<sup>6</sup>.

The receptor-mediated endocytosis of LDL was originally demonstrated in studies of human fibroblasts in tissue culture and has subsequently been found to operate in a wide variety of animal cells<sup>5,6</sup>. When cells require cholesterol for membrane synthesis, they synthesise a cell surface receptor that binds the protein component of LDL. Within 10 min of binding to the receptor, the LDL particle is internalised and delivered to lysosomes; in the lysosome the protein component is hydrolysed by proteases to amino acids and the cholesteryl esters are cleaved by an acid lipase to generate unesterified cholesterol. This unesterified cholesterol enters the cytoplasmic compartment where it serves two important functions: utilisation for membrane synthesis and regulation of key enzymes in cholesterol metabolism<sup>5,6</sup>. This latter action assures cholesterol

homeostasis in the cell as well as in the whole organism. Cytoplasmic cholesterol derived from the lysosomal hydrolysis of LDL also controls the synthesis of receptor molecules. Increased cellular cholesterol decreases the number of receptors, thereby preventing overaccumulation of LDL-cholesterol in the cell<sup>6</sup>.

The distribution of LDL receptors on the surface of fibroblasts has been studied by electron microscopy with the use of LDL coupled to the iron-containing, electron-dense protein ferritin<sup>2,19,20</sup> or by <sup>125</sup>I-LDL autoradiography<sup>27</sup>. Between 50% and 80% of all receptors are clustered over the 2% of the cell surface represented by coated pits (Fig. 1a). The membrane in these regions is indented and coated on its cytoplasmic surface by a bristle-coat. As LDL receptors are localised in coated pits even when the cells are fixed with formaldehyde prior to incubation with the LDL-ferritin, it is believed that receptor clustering occurs before the exposure to LDL<sup>19</sup>. Immunofluorescence studies with the light microscope show that the clusters of LDL receptors in human fibroblasts are aligned in linear arrays that appear to overlay actin-containing cellular stress fibres<sup>28</sup>.

LDL-ferritin bound to coated pits at 4 °C is rapidly internalised when the fibroblasts are warmed to 37 °C<sup>2</sup>. In this process the coated pits invaginate to form coated endocytic vesicles (Fig. 1a–c). After 5 to 10 min at 37 °C, LDL-ferritin is seen in lysosomes (Fig. 1d) as the result of their fusion with the

**Fig. 1** Electron micrographs showing the sequential binding of LDL-ferritin to coated pits, its internalisation in coated vesicles, and its delivery to lysosomes in human fibroblasts. Monolayers of growing human fibroblasts were incubated with growth medium containing 10% lipoprotein-deficient serum and LDL-ferritin at a concentration corresponding to  $47 \mu\text{g ml}^{-1}$  of LDL-protein at  $4^\circ\text{C}$  for 2 hours, after which the cells were washed extensively<sup>2</sup>. The cells then received growth medium containing 10% lipoprotein-deficient serum and were warmed to  $37^\circ\text{C}$ . After incubation at  $37^\circ\text{C}$  for the indicated time, the monolayers were fixed and embedded *in situ* and stained with uranyl acetate and lead citrate<sup>2</sup>. *a*, A coated pit that bound LDL-ferritin (time at  $37^\circ\text{C}$ : 1 min). *b*, A coated pit being transformed into a coated vesicle with LDL-ferritin included (time at  $37^\circ\text{C}$ : 1 min). *c*, A fully formed coated vesicle that seems to be losing its cytoplasmic coat on the right side (time at  $37^\circ\text{C}$ : 2 min). *d*, A lysosome containing LDL-ferritin (time at  $37^\circ\text{C}$ : 6 min). Magnifications: *a*,  $\times 58,000$ ; *b*,  $\times 50,500$ ; *c*,  $\times 50,000$ ; *d*,  $\times 40,000$ . Scale bars, 100 nm.

incoming coated vesicles<sup>2</sup>. The rapid sequence of events visualised in the electron micrographs of Fig. 1 precisely parallels biochemically-derived data on the rapid uptake and degradation of  $^{125}\text{I}$ -LDL<sup>10,11</sup>.

### Mutations affecting the LDL receptor

A group of naturally-occurring human mutations has been invaluable in detailing the structure and function of the LDL receptor. Those mutations responsible for the genetic disease called familial hypercholesterolaemia (FH) are most instructive<sup>5,29</sup>. Three distinct mutations seem to occur in the gene for the LDL receptor<sup>6,29,30</sup>. The most frequent mutant allele at the LDL receptor locus is designated  $R^{b0}$ ; it specifies a nonfunctional receptor. Fibroblasts from patients homozygous for this allele ( $R^{b0}/R^{b0}$ ) are unable to bind or take up the lipoprotein, even though they have normal coated pits that form normal coated vesicles<sup>19,30</sup>. A second mutation,  $R^{b-}$ , specifies a receptor that is detectable but binds <10% of the normal amount of LDL. Recently, a rare but extremely informative allele has been identified. This allele, designated  $R^{b+,i0}$ , specifies a receptor that binds LDL but does not allow the lipoprotein to be internalised<sup>11,30</sup>. The failure of internalisation is due to the inability of these abnormal receptors to be incorporated into coated pits. Although coated pits of normal appearance are present, the receptors specified by the  $R^{b+,i0}$  allele are not inside them. Instead the receptors are scattered over noncoated segments of the cell surface<sup>31</sup>.

The hypothesis that the  $R^{b+,i0}$  mutation involves the gene for the LDL receptor implies that the normal receptor must have, in addition to its LDL binding site, a second active site, the internalisation site, which is necessary for the receptor to be recognised as a component of the coated pit. The internalisation site is presumed to be on the cytoplasmic side of the membrane where it can interact with the proteins that constitute the cytoplasmic coat of the coated pit. This formulation implies that

the coat-associated proteins play an active role in the selection of receptors to be incorporated into coated pits and are therefore central to the process of receptor-mediated endocytosis<sup>30,31</sup>.

### The structural role of clathrin

Coated pits and coated vesicles were first described in mosquito oocytes by Roth and Porter, who postulated that these structures mediate the uptake of adsorbed proteins from the extracellular fluid during yolk formation<sup>32</sup>. Other investigators, including Fawcett<sup>33</sup> and Friend and Farquhar<sup>34</sup>, found that coated pits and coated vesicles mediate protein uptake in specialised cells of higher animals. Coated pits and vesicles have subsequently been found in virtually all nucleated animal cells.

Coated pits derive their name from their characteristic indented configuration and their fuzzy cytoplasmic coat. Thin section electron microscopy shows that this coat consists of periodically spaced fibres or bristles that radiate from the cytoplasmic surface (Fig. 1a-c). Coated pits have been identified in freeze-fracture electron micrographs where they exhibit a larger number of intramembrane particles than the surrounding plasma membrane<sup>20</sup>. The intramembrane particles in coated pits are approximately 20% larger in diameter than intramembrane particles in non-coated regions of membrane<sup>20</sup>. These findings suggest that coated pits contain a unique set of transmembrane proteins.

In addition to their role in endocytosis, coated vesicles have been implicated in other types of membrane transport within the cell. They are frequently found associated with the Golgi region where they appear to carry enzymes from the Golgi apparatus to the lysosome<sup>34,35</sup>. They also play a part in the secretion of proteins by mammary epithelia<sup>36</sup> and in the retrieval of excess cell surface membrane in presynaptic neurones<sup>37</sup>.

Kanaseki and Kadota first analysed the structure of coated vesicles by electron microscopy using negative staining techniques<sup>38</sup>. They showed that these structures consist of a lipid vesicle surrounded by a basket of protein that is organised in a network of hexagons and pentagons. Pearse developed a rapid method for isolating coated vesicles and made the fundamental observation that the coat of coated vesicles isolated from a variety of animal cells is composed predominantly of a single protein of molecular weight 180,000. She named this protein clathrin<sup>34,39</sup>. Figure 2 shows a stereoscopic view of the proposed structure of the protein network that forms the coat of a coated vesicle.

**Fig. 2** Proposed structure for the network of protein that forms the coat of a coated vesicle. This structure was deduced by Pearse and co-workers from electron microscopic examination of tilted views of negatively stained coated vesicles isolated from porcine brain<sup>34</sup>. The protein coat, which is organised in a network of 12 pentagons and 8 hexagons, is assembled from 108 clathrin molecules that surround a lipid vesicle. Coated vesicles having other sizes and shapes are believed to be constructed similarly with each vesicle containing 12 pentagons plus a variable number of hexagons. Redrawn from ref. 4 with permission.

Clathrin can be removed from coated vesicles by treatment with urea or protonated amines, indicating that it is non-covalently bound to the surface of the membrane<sup>40-43</sup>. With these techniques the protein has now been isolated from brain and chicken oocytes by workers in several laboratories<sup>3,4,28,39-43</sup>, and it has been shown to have important structural properties that are related to its function. For example, in specified *in vitro* conditions, clathrin will spontaneously aggregate to form a basket-like network of hexagons and pentagons similar to those that surround coated vesicles *in vivo*<sup>41-43</sup>.

An antibody to the coat protein of bovine brain coated vesicles (directed primarily against clathrin) reacts *in situ* with coated pits and vesicles in human fibroblasts<sup>28</sup>. The antigen-antibody complex can be visualised by indirect immunofluorescence using light microscopy<sup>28</sup> or by the immunoperoxidase technique in the electron microscope (Figs 3 and 4)<sup>28</sup>. In the electron microscope, the immunoperoxidase-stained clathrin can be shown to underlie coated pits (Fig. 3a), including those that have bound LDL-ferritin (Fig. 4a), as well as coated vesicles (Fig. 3b and c), again including those that have internalised LDL-ferritin (Fig. 4b). Under the light microscope, the coated pits of human fibroblasts show a linear alignment similar to the linear alignment of LDL receptors<sup>28</sup>. However, in other cells, such as Chinese hamster ovary cells, neither the LDL receptors nor the coated pits show a linear distribution, indicating that a linear arrangement is not essential for coated pit function.

### A working model for clustering of LDL receptors in coated pits of human fibroblasts

The genetic, biochemical, and morphological data obtained in the human fibroblast system have been assembled to advance a working model for the mechanism by which LDL receptors cluster in coated pits<sup>1,31</sup>. As described above, the existence of the internalisation mutation implies that the LDL receptor has two active sites—a binding site that must be on the external surface and an internalisation site that is postulated to be on the cytoplasmic surface. By analogy with other transmembrane proteins, the LDL receptor is likely to be synthesised on membrane-bound ribosomes and glycosylated in the Golgi apparatus (Fig. 5). It is then inserted into the plasma membrane at random sites. The receptor migrates laterally in the plane of the membrane until it reaches a coated pit. Interaction of the internalisation site with clathrin (or a clathrin-associated protein) fixes the receptor in the coated pit so that it is carried into the cell when the coated pit invaginates to form a coated vesicle.

Whether receptors reach the coated pits by diffusion in the plane of the membrane or whether they are actively propelled there is not known. Bretscher has suggested that the phospholipids of cell membranes continually flow towards coated pits and coated vesicles<sup>44</sup>. This flow is envisioned to result from the insertion of lipids into the membrane at remote sites with resorption in coated pits and vesicles<sup>44</sup>. If such a flow does exist, it could provide the force that carries selected receptor proteins to coated pits.

LDL receptors that enter cells in coated vesicles are not destroyed when the vesicles fuse with lysosomes. Rather, kinetic experiments suggest that the receptors return to the surface where they again cluster in coated pits; that is, they are recycled<sup>10,31</sup>. This recycling phenomenon accounts for the fact that fibroblasts ingest saturating levels of LDL at a uniform rate for more than 6 hours even when synthesis of new receptors is blocked by cycloheximide. If recycling did not occur, all of the receptors would be consumed within the first 10 minutes after exposure to LDL.

Morphological and kinetic evidence indicates that insertion of receptors into the membrane, clustering in coated pits, internalisation, and recycling occurs continuously whether or not LDL is present<sup>2,19,31</sup>. In each cycle the LDL receptor spends about 9 min on the cell surface. Assuming that LDL can bind to

the receptor at any time the receptor is on the surface, studies with LDL-ferritin indicate that in the steady state about one-third of receptors are diffusely distributed and two-thirds are clustered in coated pits<sup>2,19</sup>. Thus, in each cycle the receptor spends about 3 min in a diffuse distribution on the surface and about 6 min in coated pits. The length of time between internalisation of the receptor and its reappearance on the surface is not known, but it must be shorter than the time the receptor spends on the surface because no appreciable pool of intracellular receptors is unmasked when binding assays are performed on broken cells<sup>45</sup>. That membrane recycling can be extremely rapid has been shown by studies of the frog neuromuscular junction where the pre-synaptic coated vesicles recycle within seconds<sup>37</sup>.

Other explanations for the morphological and kinetic data in fibroblasts are possible. For example, rather than being recycled it is conceivable that the LDL receptor never actually leaves the surface. That is, as the coated pit pinches off, the LDL is transferred from the receptor to some other carrier with the receptor escaping inclusion in the coated vesicle and thus remaining on the cell surface. While such a mechanism would be consistent with all current data, there is no direct evidence to support it.

The model for insertion of the LDL receptor into coated pits by lateral movement within the plane of the plasma membrane resembles an earlier model advanced for the assembly and secretion of lipid-envelope viruses in animal cells (reviewed in ref. 46). When the vesicular stomatitis virus replicates in cultured animal cells, it produces a messenger RNA for a transmembrane glycoprotein, the G protein, that is synthesised on host membrane-bound ribosomes and inserted at random

**Fig. 3** Electron micrographs showing the localisation of clathrin in human fibroblasts as determined with the indirect immunoperoxidase technique. Monolayers of fibroblasts were fixed with 3% formaldehyde. The membrane was then made permeable with 0.05% Triton X-100, and the cells were incubated first with rabbit anti-coat protein  $\gamma$ -globulin (directed primarily against clathrin) and then with goat anti-rabbit IgG that was coupled to horseradish peroxidase. The cells were then stained for peroxidase as previously described<sup>28</sup>. *a*, Peroxidase-positive indented regions of cell surface membrane (arrows). These regions have the typical shape of coated pits. The normal trilaminar appearance of the membrane has been destroyed by the Triton X-100 preparation procedure. *b*, and *c*, show peroxidase-positive endocytic vesicles (arrows) that have the morphology of coated vesicles. All micrographs are of unstained material. Magnifications: *a*,  $\times 21,500$ ; *b*,  $\times 20,000$ ; *c*,  $\times 21,500$ .

sites into the plasma membrane. The G proteins then gather together to form a patch of plasma membrane that ultimately becomes the envelope of the virus. This clustering of G proteins is mediated by their association with a cytoplasmic protein, the M protein, that is also coded by the viral genome but is synthesised on free ribosomes. The patch of membrane containing G and M proteins serves as the site of attachment of the viral nucleocapsid during viral budding. In the two models, the G protein is analogous to the LDL receptor, the M protein is analogous to clathrin, and the developing patch of viral envelope membrane is analogous to the coated pit. If the two working models prove to be correct, they would suggest a general principle: membrane structures such as viral patches and coated pits are assembled within the plane of the membrane by the interaction of transmembrane proteins with cytoplasmic organiser proteins.

### Variations on a common theme

Table 1 lists the protein ligands for which receptor-mediated endocytosis has now been demonstrated. In each of these systems, uptake of the protein follows rapidly upon binding. In each case the endocytosis is carried out by the same receptor that is believed to mediate the physiologic action of the protein. For six of the systems, including the receptors for LDL<sup>2,19,20,27</sup>, yolk proteins<sup>21,32</sup>, transferrin<sup>22</sup>, epidermal growth factor<sup>23</sup>,  $\alpha$ -2-macroglobulin<sup>24</sup>, and maternal immunoglobulins (IgG)<sup>21,47-49</sup>, internalisation has been shown by electron microscopy to occur in coated pits and coated vesicles. In addition, evidence from the light microscope suggests that insulin enters mouse 3T3 cells through this route<sup>50</sup>. In the other systems listed in Table 1, internalisation via coat pits and coated vesicles has not yet been visually demonstrated. However, in the case of transcobalamin II<sup>14,51</sup>, chorionic gonadotropin<sup>15</sup>, and asialoglycoproteins<sup>16,17</sup>, uptake rapidly follows binding, indicating a close coupling between the two events and in turn suggesting that coated pits may be involved.

In those systems for which coated pits have been documented, the mechanism for receptor clustering into the pits may vary. As described above, LDL receptors seem to be incorporated into coated pits by virtue of their internalisation sites in a process that is independent of LDL binding. One electron microscopic study of epidermal growth factor binding to human fibroblasts suggests that a significant proportion of these receptors behave similarly to those for LDL; even when epidermal growth factor was added in conditions in which lateral diffusion was inhibited by chilling the cells to 4 °C, 34% of the factor bound within coated pits, presumably to receptors that were already located there<sup>23</sup>. On the other hand, light microscopic studies with fluorescent-labelled epidermal growth factor in mouse 3T3 cells suggest that most of the receptors are distributed diffusely when binding is conducted at 4 °C<sup>50</sup>. Receptor clustering in coated pits was observed only after the cells were warmed to 37 °C in the presence of epidermal growth factor. Similar results were reported for fluorescent-labelled  $\alpha$ -2-macroglobulin and insulin in the same cell type<sup>50</sup>. The simplest, but not necessarily the correct, explanation of this discrepancy is that some receptors may reach coated pits as a result of a receptor-mediated mechanism, while others may require a ligand-mediated event.

In three of the systems in Table 1—LDL<sup>10,52</sup>, transcobalamin II<sup>14,51</sup>, and asialoglycoproteins<sup>16,53</sup>—new receptors are efficiently regenerated, probably by recycling of internalised receptors, after the ligand is carried into the cell. As a result, cells internalise these ligands for hours at a steady rate. On the other hand, when epidermal growth factor is incubated with fibroblasts, the initial wave of receptor-mediated endocytosis leads to a rapid 80% depletion in the number of surface receptors<sup>13,53,55</sup>. This reduction has been attributed to a degradation of the internalised epidermal growth factor-receptor complex, which is not accompanied by a reappearance of new receptors. In the continued presence of epidermal growth factor, cells establish a new steady state in which they bind,

**Fig. 4** Electron micrographs showing the binding of LDL-ferritin to clathrin-containing regions of cell membrane. Monolayers of human fibroblasts were chilled to 4 °C and incubated with LDL-ferritin at a concentration corresponding to 22  $\mu\text{g ml}^{-1}$  of LDL-protein for 30 min. The cells were then warmed to 37 °C for 8 min, washed at 4 °C to remove excess LDL-ferritin, fixed with 3% formaldehyde, and made permeable with 0.05% Triton X-100. The cells were then processed for indirect immunoperoxidase localisation of anti-clathrin binding sites as described in the legend to Fig. 3. *a*, Ferritin cores associated with an indented, peroxidase-positive segment of membrane that has the typical morphology of a coated pit, indicating that LDL-ferritin and the antibody directed against clathrin bind to the same region of surface membrane. *b*, Ferritin cores contained within endocytic vesicles that are rimmed by peroxidase reaction product that delineates the clathrin coat. All micrographs are of unstained sections. Magnification,  $\times 100,000$ .

internalise, and degrade the hormone continuously at about 20% of the initial rate. Whether receptor recycling occurs during this steady state is not known.

Whereas the coated pit-coated vesicle seems to be a common portal of entry for receptor-bound proteins, the ultimate destinations of these proteins vary. In seven of the systems in Table 1, the internalised protein (radiolabelled with <sup>125</sup>I in tyrosine residues) is rapidly degraded<sup>6,12-18,25,56-59</sup>. In these systems, no significant amounts of radiolabelled products other than <sup>125</sup>I-monoiodotyrosine are formed by the cells. This suggests the concerted action of multiple proteases and thus implicates lysosomes<sup>56,57</sup>. Moreover, in each of these systems, degradation of internalised protein is blocked by the lysosomal enzyme inhibitor chloroquine<sup>6,13-15,17,25,57</sup>. For LDL<sup>2,52</sup> and epidermal growth factor<sup>23</sup>, lysosomal delivery has been demonstrated directly by electron microscopy.

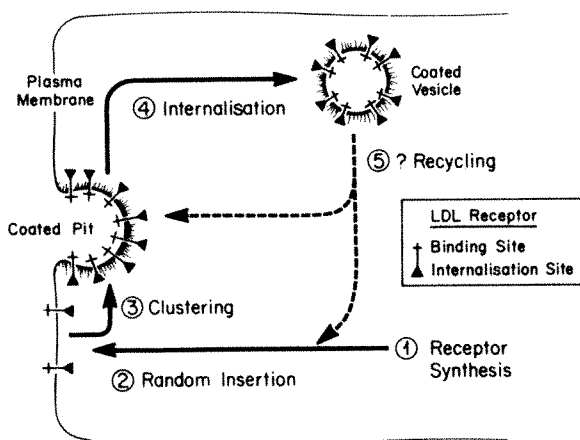

Some of the proteins that enter cells through receptor-mediated endocytosis are not degraded but instead are directed to specific subcellular organelles. For example, yolk proteins accumulate in yolk granules apparently without degradation<sup>21,32</sup>. Nerve growth factor, which enters the cell at the tip of the axon, migrates in vesicles to the cell body where it apparently accumulates in an intact form<sup>62</sup>. Although most of the receptor-bound insulin that enters cells is degraded in lysosomes<sup>12,25</sup>, some fraction of receptor-bound hormone may be delivered to the Golgi apparatus<sup>61</sup> and to nuclei<sup>64</sup>. Lysosomal enzymes that are secreted by cells re-enter the cells through

receptor-mediated endocytosis and accumulate within lysosomes and Golgi-associated structures where they remain active for many days<sup>65-67</sup>. Finally, maternal immunoglobulins (IgG), which enter the fetal yolk sac or the neonatal intestinal epithelial cell at the apical surface, are transported intact in coated vesicles to the basal surface where the IgG molecules are discharged into the fetal or neonatal circulation<sup>21,47-49</sup>.

An important question posed by the above findings relates to the mechanism by which endocytic vesicles and their contents are directed to specific delivery sites within the cells. Do proteins with different destinations enter cells in the same vesicles? If so, how are these proteins sorted and delivered to their separate destinations?

It should be pointed out that receptor-mediated endocytosis is not the only way in which proteins can enter animal cells. At least two other mechanisms exist. First, extracellular proteins are trapped nonselectively in fluid droplets that are internalised by cells through the invagination of noncoated regions of membrane<sup>7</sup>. To date, no receptor-bound protein has been demonstrated to enter cells through such noncoated vesicles. Second, some bacterial and plant toxins and certain viruses appear able to enter cells by direct penetration through the plasma membrane. Direct penetration of physiological molecules, such as protein hormones, has not yet been demonstrated.

**Fig. 5** Working model for the mechanism by which LDL receptors cluster in coated pits on the plasma membrane of human fibroblasts. The postulated steps are as follows: (1) synthesis of LDL receptors on polyribosomes; (2) insertion of LDL receptors at random sites along noncoated segments of plasma membrane, (3) clustering of LDL receptors in clathrin-containing coated pits, (4) internalisation of LDL receptors as coated pits invaginate to form coated endocytic vesicles, and (5) recycling of internalised LDL receptors back to the plasma membrane. It seems likely that the clathrin is also recycled and reutilised. Reprinted from ref. 31 with permission.

## Why do cells need receptor-mediated endocytosis?

The studies cited in this review demonstrate that coated pits and coated vesicles function as transport organelles that carry selected receptor-bound proteins into cells in a tightly controlled fashion. It is easy to understand the need for such a system when cells are dealing with transport proteins such as LDL, yolk proteins, transferrin, and transcobalamin II. The reason for such a sophisticated mechanism of uptake for protein hormones is not yet clear. At the very least, the receptor-mediated uptake and degradation systems serve to degrade the protein hormones so that they, and in some cases their receptors, can act only once. But is this the only reason for receptor-mediated endocytosis of protein hormones? Does the endocytic uptake mediate any of the actions of the hormones? To date, no regulatory action of a

protein hormone (with the possible exception of nerve growth factor) has been shown to require endocytosis of the protein. Moreover, some events, such as insulin-mediated stimulation of glucose transport, occur too rapidly to be accounted for by endocytosis.

To date, only a few studies have addressed the question of whether the long-term biological effects of protein hormones require endocytic uptake. More systems are needed in which the entire sequence of hormone binding and hormone action can be studied by combined biochemical and morphological techniques in isolated cells. Such studies would be facilitated by the availability of cells bearing naturally-occurring or experimentally-induced mutations in the sequence between hormone binding and hormone action. With the process of receptor-mediated endocytosis now in focus and with the powerful tools of cell biology and somatic cell genetics at hand, it seems likely that such systems will be developed and that answers to the questions posed in this review will be forthcoming in the near future.

## Non-exponential decay in dielectrics and dynamics of correlated systems

L. A. Dissado & R. M. Hill

Chelsea College, University of London, Pulton Place, London SW6, UK

*A new model for the relaxation of a potential perturbation in dielectric materials is developed based on the correlated properties of a two-level system containing two types of decay mechanism. The time and frequency behaviour of the general relaxation process is shown to be in accord with recent experimental analyses. The technique developed to analyse the model is of general applicability in the solid, and liquid, state.*

It has been shown<sup>1</sup> previously that for materials exhibiting a dielectric loss peak the magnitude of the imaginary part of the susceptibility, as a function of frequency, obeys the empirical relationship

$$\chi''(\omega) = \frac{\omega^m}{(\omega_p^{2s} + \omega^{2s})^{(1-n+m)/2s}} \quad (1)$$

where  $0 \leq m, n$  and  $s \leq 1$ . In the post-peak region,  $\omega > \omega_p$ , this relationship can be written in the form  $\chi''(\omega) \propto (\omega)^{-(1-n)}$  and Jonscher<sup>2-5</sup> has suggested that the behaviour can best be understood as

$$\chi''(\omega)/\chi'(\omega) = \cot(n\pi/2) = \text{constant} \quad (2)$$

which states that the ratio of the energy lost to the energy stored is a constant. In the pre-peak region the imaginary part of the susceptibility exhibits a power law dependence,  $\omega^m$ , and equation (2) is not obeyed. The empirical equation (1) describes a complete decay characteristic for the materials exhibiting loss peaks. It can be Kramers–Kronig transformed to give  $\chi'(\omega)$ , and agreement with experimental measurements has been observed. We use here the presence of a loss peak to define our term dipolar dielectric, and we shall only consider this class of materials.

The universal equation (2) requires the susceptibility to follow a power law in time ( $t^{-n}$ ) in the equivalent, short time, region. It has recently been postulated by Ngai *et al.*<sup>6</sup> that the origin of this form of decay lies in an infrared divergence mechanism and that

the basic requirements for the application of this mechanism in a wide range of systems have been established computationally.

Starting from the concept of an assembly in which the local units possess two equilibrium positions<sup>7,8</sup> (a two-level system) we will show that the consequence of interaction between the local units leads to a complete description of the susceptibility of dipolar dielectrics. The post-peak behaviour arises naturally from this description. The method used is powerful and yields detailed and quantitative information on the microscopic structure and its dynamics. As the final expressions describe the macroscopic behaviour they can be conceived in a variety of ways and reveal the flexibility of the approach presented here. The results of this analysis have a wide range of applicability outside purely dielectric behaviour and similar approaches should be generally applicable.

### The $t^{-n}$ behaviour

Before describing dielectric relaxation in terms of the cooperative model we must describe briefly the origins and requirements of the  $t^{-n}$  behaviour, which is a special case of the time development of transients<sup>9</sup>. Consider a system divided into two interacting sub-systems. The first of these responds rapidly to a stimulus generating a change in the interaction which, in turn, causes a much slower response of the second sub-system. The state of the total system then corresponds to the excited first system together with the unresponded second system, and can be considered as a transient or metastable state which slowly decays as the second system responds. In this way a Franck–Condon progression is developed in molecular spectra<sup>10-12</sup>, the fast system being a high frequency transition which is coupled to the slow response of a discrete spectrum of low frequency oscillations.

The special requirements for a  $t^{-n}$  behaviour are<sup>13</sup>: (1) a continuous spectrum of slow responders extending to zero frequency; (2) a constant density of transition states, per unit energy, for the slow system, in the same energy range; (3) an effective population distribution in the slow states such that they can be regarded as either fully occupied or unoccupied only.

The time behaviour of the state vector of the transient can be obtained from the total hamiltonian  $H$  as

$$\exp(-iHt) = \langle t|0 \rangle \quad (3)$$

which in second order perturbation theory<sup>10,14</sup>, in energy/frequency normalised units, becomes

$$\exp(-iEt) \cdot \exp\{-F(t)\} \quad (4)$$

with  $E$  the unspecified excitation energy of the transient, and

$$F(t) = i n \zeta t - \int_0^t \frac{|VN|^2}{u} \{1 - \exp(-iut)\} du \quad (5)$$

$N$  is the total number of slow responders and  $\zeta$  is their maximum excitation energy, the constant density of states is thus  $N/\zeta$ .  $V$  is the interaction change brought about by the fast excitation and  $u$  the energy difference for nett excitations within the slow response system. Equation (5) is obtained by allowing  $V$  to cause excitations and de-excitations in the slow system, the double sum over initial and final states being replaced by the already completed sum over initial states, for a given energy difference  $u$ , and an integration over  $u$ . This is shown in Fig. 1.

The average energy change per fast excitation will be distributed over the  $N$  slow responders and is  $NV$ . As  $\zeta$  is the maximum excitation energy,  $|NV|^2/(\zeta)^2$  is less than unity and is set equal to  $n$ . Integrating equation (5)<sup>13,15,16</sup> gives

$$F(t) = i n \zeta t - n \{ \gamma + \ln(i \zeta t) + E_1(i \zeta t) \} \quad (6)$$

where  $\gamma$  is Euler's constant and  $E_1(iz)$  an exponential integral<sup>17</sup>. For short times, such that  $t \zeta < 1$

$$F(t) \rightarrow 0 \quad (7)$$

and the transient oscillates with its excitation frequency corresponding to the energy  $E$ . At long times ( $t \zeta > 1$ )

$$F(t) = \exp\{-i(E - n \zeta)t\} \cdot \exp(-n \gamma) \cdot \exp(i n \pi / 2) \cdot (t \zeta)^{-n} \quad (8)$$

where the excitation energy of the transient has been reduced by  $n \zeta$ , and the transient decays as  $t^{-n}$ .

In applying this result to our problem the fast excitations and the slow responders are assumed to lie in the same continuum of states, the slow responders merely being slower than a particular fast transient excitation within the same total system. The system returns to its unexcited state by means of excitations of the slow responders, which decay monotonically. For this reason  $E$  is taken equal to  $n \zeta$ , and it has already been shown that  $n$  lies between zero and unity corresponding to no excitation or total excitation of the system respectively. Note that any observable property of the transient follows a behaviour governed by the real part of equation (4), and thus oscillates with diminishing frequency while decaying as  $t^{-n}$ .

**Fig. 1** The two-level system: the range of initial states available for excitation with energy  $u$  is shown by cross hatching. The equivalent number of initial states is  $(Nu/\zeta)$  where  $N/\zeta$  is the constant energy density.

## Interacting two-level systems

A local two-level system can be considered as a group of atoms, ions or molecules possessing two equilibrium configurations separated by a small energy difference and between which local tunnelling is allowed<sup>7,8</sup>. Such a system can be described by a spin

formalism in which the energy tensor is

$$\begin{pmatrix} B_e & U_e \\ U_e & -B_e \end{pmatrix} \quad (9)$$

where  $B_e$  is half the energy difference between local potential minima and  $U_e$  is the off-diagonal tunnelling (transition) element. Such systems can couple to elastic deformations and have been used to describe a range of glass properties<sup>18</sup>. When the local system possesses a dipole moment the coupling to an electric field takes the form

$$\begin{pmatrix} d & \mu \\ \mu & -d \end{pmatrix} F \quad (10)$$

with the off-diagonal elements  $\mu$  allowing a resonance absorption, the diagonal elements a relaxation spectra. A spin-spin interaction arises from the coupling of pairs of local spin systems through the off-diagonal elements of the tensor in equation (9). These interact with phonons and give the usual dipolar spin-spin interaction through a virtual two-phonon exchange mechanism<sup>19</sup>. The spin-spin interaction can be regarded as a perturbation on an unperturbed local system with energy levels  $\pm B_e$  together with a local transition interaction. It contains three types of term, each of which has a definite and unique influence on the overall system.

(1) The secular interaction: this is a dipole-dipole cooperative interaction which contributes to the energy of each unperturbed spin. It is the basis of the Ising hamiltonian and when calculated in the mean field approximation has a contribution to  $B$  of  $T_c M$ , where  $M$  is the mean value of the  $z$  component of the local dipole unit vector, in this case electric, and  $T_c$  is a characteristic parameter of the system. The system can no longer be regarded as a set of local systems because of the cooperative interaction. Its energy levels are macroscopic and the macroscopic thermal average,  $M_e$ , of  $M$  is

$$M_e = \tanh\left(\frac{B + k T_c M_e}{k T}\right) \quad (11)$$

which is a consequence of the condition that the dipoles can only be in one of two states.  $B$  is the average of  $B_e$  over all the system, and the dipole of the system in equilibrium is  $N M_e d$ . The value of  $M_e$  is defined by equation (11) and is determined from  $B$ ,  $T_c$  and the temperature  $T$ . The energy  $B$  can be regarded as the splitting of a two-level system by a well-defined internal field. In amorphous glassy systems the local value of  $B_e$  is not constant but takes a continuous range of values with a constant number density at each value<sup>19,20</sup>. It has been suggested<sup>6</sup> that this applies to a wide variety of materials.

(2) The flip-flop interaction: this interaction allows a pair of dipoles to exchange spins synchronously and without altering  $M$ . Local spins move through the whole system by this mechanism. The time taken to complete a spin exchange is

$$t_e \approx \pi / V_{ff} \quad (12)$$

where  $V_{ff}$  is the flip-flop interaction energy. The time has been estimated as  $10^{-8}$ – $10^{-10}$  s (ref. 19).

On a time scale greater than  $t_e$  the local spins will sample the whole of the local values of  $B_e$ . In general those local spins whose values of  $B_e$  differ by less than the maximum value of the interaction energy,  $V_{ff \max}$ , can be regarded as in resonance and hence involved in a true spin-spin exchange. Those spins with a greater difference than  $V_{ff \max}$  interact in an off resonance manner and do not have a true spin-spin exchange.

In this way, on a time scale greater than  $t_e$ , the macroscopic value of  $B$  in equation (11) will alter without altering  $M_e$ . But the nature of equation (11) requires an alteration in  $B$  to generate a consequent change in  $M_e$ . Thus the flip-flop interaction has to be regarded as causing fluctuations in  $M_e$  about a well defined average.

(3) The raising and lowering interaction: this interaction couples  $M$  with raising and lowering operators. These operators allow excitation and de-excitation of the unperturbed local

system, and generate absorptions at multiples of the Larmor frequency in nuclear magnetic resonance spectra<sup>21</sup>. When paired together the value of  $M$  is unchanged and oscillations are generated at frequencies equal to the difference between excited and unexcited local systems<sup>22</sup>. Since the frequencies span the range from zero up to a particular maximum they can be regarded as a system of slow responders.

All spins will be connected by this interaction, hence a fluctuation such as a flip-flop interaction will create a transient which decays as  $t^{-m}$  as the frequencies less than  $V_{ff \max}$ , that is,  $10^8$ – $10^{10}$  Hz, respond. The magnitude of the parameter being given by

$$m = (V_{ff \text{ average}} / V_{ff \max})^2 \quad (13)$$

## The rate equation

The fundamental concepts required to establish the framework of our approach have already been established. The basic model is that a deviation from equilibrium in a macroscopic system resulting from the application or removal of an external field is restored to an equilibrium that is itself fluctuating on a long time scale. Because of the connection between  $M$  and  $B$  in equation (11) fluctuations in the ground state energy  $B$  must affect the rate of restoration of equilibrium. Calculations using this model are applicable to many fields but we shall consider here a dipolar dielectric.

The dipolar dielectric is represented by a double minimum in the total (macroscopic) free energy as indicated in Fig. 2. Each minimum refers to a set of configurations of local dipoles with their orientations effectively in one of two alternative directions. Each configuration is thus specified by a set of local dipole orientations, simultaneously fully occupied, which have an equal number of unoccupied levels belonging to a configuration with an opposing dipole orientation and separated from them by a large potential barrier. The two sets of configurations are therefore only accessible to each other either by thermally activated or tunnelling processes. Thermal equilibrium is established between groups of macroscopic configurations rather than independent local orientations.

After the removal of an externally applied perturbing influence there are two competing relaxation processes as well as the fluctuations to consider. These are thermal activation and local tunnelling, (Fig. 2c and b).

The rate equation for the thermal process can be written as<sup>23</sup>

$$\frac{dM}{dt} = -\nu_E \cosh\left(\frac{B + kT_c M}{kT}\right) \left\{ M - \tanh\left(\frac{B + kT_c M}{kT}\right) \right\} \quad (14)$$

where  $\nu_E$  has an activated form with a pre-exponential frequency of the order of  $10^{13}$  Hz, that is

$$\nu_E = \nu_0 \exp(-\Delta/kT) \quad (15)$$

Writing

$$M = M' + \tanh\left(\frac{B + kT_c M_c}{kT}\right) = M' + M_c \quad (16)$$

a linear form of equation (14), exact in  $M_c$ , can be found,

$$\begin{aligned} \frac{dM'}{dt} &= -\nu_E \cosh\left(\frac{B + kT_c M_c}{kT}\right) [M' \{1 - (1 - M_c^2) T_c / T\}] \\ &= -\omega_p M' \end{aligned} \quad (17)$$

where  $M'$  is the deviation from equilibrium of  $M$ .

As  $\omega_p$  involves  $M_c$  it can be considered as an expectation value of an operator in the fluctuating system. Thus the rate itself fluctuates and must be averaged over these fluctuations in  $\omega_p$ . To carry out this averaging, the form of the equilibrium fluctuations must be determined.

Resonance flip-flops exchange dipoles between the two minima, in each of which a new configuration is generated. The initial equilibrium value of  $B$  of the macroscopic state is not appropriate to the new configurations and the state evolves in

Fig. 2 A double minima potential. a, A tunnelling process of synchronous excitation and de-excitation. b, A cooperative tunnelling relaxation process. c, A thermally activated relaxation process.  $\Delta$ , the average energy of the maximum above the two minima.

time to accommodate the change. The state of the configuration in each minimum immediately following a flip-flop will effectively be that due to the excitation of a dipole from a fully occupied to a non-occupied level. The population criterion (3) for the slow responders is completely fulfilled and the time evolution of each configuration, and hence the system, follows a time power law, the exponent of which has been defined as  $m$ .

During the transient decay the requirement of a well defined average necessitates a balance which arises from the multiply-connected pairs between the two configurations of the transient, generating a new equilibrium state of the system that satisfies equation (11).

The fluctuations must therefore follow a time development of the form

$$(t - t_1)^m \cdot t_1^{-m} \quad (18)$$

as the balancing is delayed in time by  $t_1$  to allow for the initial decay. Equation (18) represents fluctuations about a well defined average expectation value because of the constant time average

$$t^{-1} \int_0^t (t - t_1)^m \cdot t_1^{-m} dt_1 = \Gamma(1 + m) \cdot \Gamma(1 - m) \quad (19)$$

To allow for these fluctuations a time average has to be taken in the rate equation, equation (17),

$$\left\langle \frac{dM'}{dt} \right\rangle \propto -\omega_p(t)^{-1} \int_0^t (t - t_1)^m t_1^{-m} M'(t - t_1) dt_1 \quad (20)$$

The evolution of the initial state,  $t_1^{-m}$ , competes with the thermal decay process, but the balancing  $\{(t - t_1)^m\}$  initiated by the decay at  $t_1$  generates a new macroscopic state satisfying the initial conditions and thus initiates a new contribution to the relaxation, giving the composite relaxation rate at time  $t$  shown in equation (20). The value of  $M'(t - t_1)$  is evaluated from

$$\frac{d\{M'(t_s - t_1)\}}{d(t_s - t_1)} = -\omega_p(t_s - t_1)^m t_1^{-m} M'(t_s - t_1) \quad (21)$$

giving

$$\ln[M'(t_s)/M'_{(0)}] = -\omega_p \int_0^{t_s} (t_s - t_1)^m t_1^{-m} d(t_s - t_1) \quad (22)$$

and hence, using equation (20), and normalising to unity,

$$M'(t - t_1) = M'_{(0)} \exp\{-\omega_p(t - t_1)\} \quad (23)$$

The variable in equation (21) is the time span,  $(t_s - t_1)$ , during which the relaxation proceeds uninterrupted as opposed to the actual time,  $t$ , at which measurements are made.

The initial deviation from equilibrium,  $M'_{(0)}$ , arises from the removal of a perturbation which alters  $B$ , for example an external electric field which makes a contribution  $Fd$  to  $B$  where  $d$  is the local  $z$  component of the dipole moment, and is given by

$$M'_{(0)} = \tanh\left(\frac{B + Fd + kT_c M'_{(0)}}{kT}\right) - M_c \quad (24)$$

That is,  $F$  rotates the macroscopic dipole towards or away from the fixed internal field direction.

The rate constant  $\omega_p$  is the maximum probability that a thermally activated process leads to a transition of a dipole between alternate minima. The activated factor is the probability for a thermal process of sufficient energy to surmount the barrier, and the pre-exponential factor is the quantum mechanical transition rate at the barrier peak.

A second independent relaxation process, that of local tunnelling, may also occur. Each tunnelling event takes place in a time of approximately  $\nu_0^{-1}$  and flips a dipole from one minimum to the other. A transient configuration is thus created in each well in a manner similar to that generated by flip-flops, and which decays by a time power law with a different exponent,

$$\cos(n\pi/2) \cdot (t\zeta)^{-n} \quad (25)$$

the range of frequencies,  $\zeta$ , in the slow system being from zero up to  $\nu_0$ , or the maximum value in the system, whichever is lower. This behaviour describes the tunnelling relaxation of a deviation in  $M$ , and in this case there is no balancing time behaviour. The magnitude of  $n$  is proportional to the amount of configuration change introduced by exciting a single dipole, as a fraction of the maximum possible change, and is therefore the degree of cooperation of dipole tunnelling.

Fig. 3 A log-log plot of the decay current as a function of time. The power law limiting behaviour regions can be clearly seen.

This cooperative tunnelling relaxation process competes independently with the thermally activated relaxation, equation (23), and takes place on the same time scale. Therefore, at a time  $t-t_1$  after the relaxation has been initiated at  $t_1$ ,  $M'$  has relaxed to

$$M'(t-t_1) = M'_{(0)} \cos(n\pi/2) \cdot [\zeta(t-t_1)]^{-n} \exp\{-\omega_p(t-t_1)\} \quad (26)$$

The value of the relaxation current observed at time  $t$  is that given in equation (20) with  $M'(t-t_1)$  given in equation (26) and is

$$\begin{aligned} \left\langle \frac{dM'}{dt} \right\rangle &= \frac{\omega_p \cos\left(\frac{n\pi}{2}\right) \zeta^{-n} \int_0^t (t-t_1)^{n-1} M'_{(0)} (t-t_1)^{-n} e^{-\omega_p(t-t_1)} dt_1}{\int_0^t (t-t_1)^{n-1} dt_1} \\ &\propto \omega_p \cos\left(\frac{n\pi}{2}\right) \zeta^{-n} M'_{(0)} e^{-\omega_p t} t^{-n} {}_1F_1(1-m; 2-n; \omega_p t) \end{aligned} \quad (27)$$

where  ${}_1F_1(;;)$  is the confluent hypergeometric function<sup>24</sup>. Equation (27) describes a complex situation. An initial deviation decays through two independent processes. One is an internal readjustment, and is described by the  $t^{-n}$  behaviour. The other is a thermal decay process in which the rate constant fluctuates about an average value. These fluctuations are the result of a

second microscopic interaction. The composite rate observed at time  $t$ , therefore, has to be averaged over the fluctuations. A linear Ising model calculation of configuration correlation functions<sup>25</sup> has revealed some of the features of the above expression.

## Frequency-dependent susceptibility

To obtain the linear frequency-dependent susceptibility a form of  $\langle dM'/dt \rangle$ , equation (26), requires to be determined in which the initial deviation from equilibrium is linear in field strength. Expanding equation (24) gives

$$M'_{(0)} = \frac{Fd}{kT} (1-M_e^2) \{1 - (1-M_e^2)T_c/T\}^{-1} \quad (28)$$

The frequency dependence of the susceptibility is given by a standard transformation of equation (26). The time development of equation (26) is shown in Fig. 3. At short times the confluent hypergeometric function has a limiting value of unity, as has the exponential term, and hence

$$\left\langle \frac{dM'}{dt} \right\rangle = J \propto (\omega_p t)^{-n} \quad (29)$$

where  $J$  is the decay current. At infinite time the asymptotic form of the hypergeometric term is proportional to  $\exp(+\omega_p t) \cdot (\omega_p t)^{n-m-1}$  and the equivalent current is given by

$$(\omega_p t)^{-(1+m)} \quad (30)$$

In the limited region around  $t \approx \omega_p^{-1}$  the decay is dominated by the exponential term. The Laplace transform of equation (26) is<sup>26</sup>, in normalised form,

$$\chi(\omega) \propto \frac{\omega_p^{1-n}}{(\omega_p + i\omega)^{1-n}} \cdot {}_2F_1\left(1-n, 1-m; 2-n; \frac{\omega_p}{(\omega_p + i\omega)}\right) \quad (31)$$

in which  ${}_2F_1(;;)$  is the gaussian hypergeometric function<sup>26</sup>. Equation (31) has the simple asymptotic behaviour that at frequencies greater than  $\omega_p$  both the real and imaginary parts of the complex susceptibility are proportional to  $\omega^{-(1-n)}$ , in agreement with equations (1) and (2). At frequencies less than  $\omega_p$  the imaginary part of the susceptibility is proportional to  $\omega^m$  and the real part is given by  $\chi'_{(\omega=0)} - A\chi''_{(\omega)}$  where  $A$  is a constant, in agreement with equation (1). The curvature parameter  $s$  of equation (1) is found to be a single-valued function of  $m$  and  $n$ .

The particular value of  $m$  equal to unity is of interest as it can arise either when there is perfect correlation in the flip-flop processes, or when measurements are made at sufficiently high frequencies that the slow responders cannot give rise to the fluctuation process. Both forms have been observed experimentally<sup>1</sup>.

## Discussion

The basic requirements for the present model is the presence of a set of two-level systems in which the frequency difference ranges from zero upwards, and in which the number density is effectively constant. The existence of these states has been demonstrated experimentally in glasses<sup>19</sup> and theoretically established in other materials<sup>6</sup>; from this the high frequency behaviour follows. It should be pointed out that most dielectric susceptibility measurements are made close to a phase transition<sup>27,28</sup> where a cooperative system of structural changes with at least two local potentials must exist. The local two-level system considered here can be regarded as describing the structural changes involved in a phase transition. The processes described here are the microscopic reality behind Jonscher's 'screened hopping model'<sup>29</sup>. The exponents  $n$  and  $m$  have been determined as follows;  $m$  is the degree of structural adjustment required for the average flip-flop process. It is therefore a correlation of these processes in the ground state.  $n$  is the degree

of structural adjustment required for the average spin flip (spin raised or lowered). It is thus a correlation factor for the dynamic restorative tunnelling events.

It is expected that mechanical strain, nuclear magnetic resonance  $T_1$  measurements<sup>30</sup>, magnetic susceptibility and the molecular dynamics of plastic crystals will show similar behaviour<sup>28</sup>. In particular ultrasonic absorption measurements in which the pseudo-spins respond to variations in  $B$  produced by acoustic vibrations show a similar response<sup>31</sup>.

Finally we point out that a non-exponential decay behaviour is a theoretical necessity in all systems which do not have an infinite range of energy in their decomposed state<sup>32</sup>, for example which may recombine. The required behaviour has to be faster

than exponential at short times and slower than exponential at long times. The transitional behaviour between these regions is close to exponential in form, as it is here. Usually the available experimental time region is such that only minor deviations from an exponential behaviour can be observed. Because dielectric susceptibility is observable over wide ranges of frequency and amplitude, and is amenable to temperature scaling, it provides a unique opportunity to study the details of the non-exponential decay and the microscopic mechanisms involved.

We thank the SRC for an assistantship for L.A.D., and A. K. Jonscher for his continued assistance and encouragement.

# Thermal aspects of komatiite generation and greenstone belt models

B. L. Weaver & J. Tarney

Department of Geological Sciences, University of Birmingham, UK

*Thermal modelling suggests that the problems posed by the high liquid temperatures ( $\sim 1,650^\circ\text{C}$ ) of peridotitic lavas in Archaean greenstone belts, and the implied high degree of mantle melting ( $\sim 70\%$ ), are significantly reduced by considering uprise of a more refractory mantle diapir having an inherent density contrast with the surrounding mantle, and in a tectonic environment analogous to a marginal basin.*

LAVAS of komatiitic composition<sup>1,2</sup>, representing very high magnesian liquids with up to 33% MgO, are a common and distinctive magma type in Archaean greenstone belts, although comparable high magnesian liquids become increasingly rare in younger post-Archaean volcanic provinces. They occur most frequently in the lower parts of greenstone volcano-sedimentary sequences, where there may be several cycles of ultramafic-mafic lavas. Although crystal fractionation has been demonstrated in some ultramafic-mafic lavas<sup>3</sup>, the presence of spinifex quench textures<sup>4</sup> indicates that in most cases the high-MgO character is primary and not due to olivine accumulation. Deriving such highly magnesian liquids by mantle fusion poses severe thermal problems.

Experimental studies<sup>5</sup> have shown that the high liquidus temperatures of peridotitic komatiite ( $\sim 1,650^\circ$  at 1 atm) would require  $\sim 70\%$  partial melting of mantle pyrolite. Similar melting experiments on mantle nodules<sup>6</sup> have also demonstrated

that high degrees of melting would be required to produce peridotitic komatiite liquids. Modelling of the thermal evolution of ascending pyrolite diapirs<sup>7,8</sup> indicates that attainment of this high degree of partial melting would necessitate initiation of mantle diapirs from depths in excess of 300 km. This somewhat extreme requirement has led to suggestions<sup>8</sup> that the mantle source regions may have been enriched in radioactive heat-producing elements.

Recent detailed geochemical studies of Archaean greenstone volcanic sequences in Canada, Australia, Rhodesia, South Africa and Finland<sup>9-12</sup> have shown, however, that many peridotitic komatiite lavas not only have low trace element abundances, as may be expected with high degrees of mantle melting, but also have light rare-earth depleted rare-earth element patterns and low incompatible element abundances (Fig. 1). These features have been taken as indicating that such peridotitic komatiites are derived from a 'depleted' mantle source<sup>12</sup> similar to that for modern mid-ocean ridge basalts, and are most unlikely to have been enriched in U, Th, K and Rb. Other peridotitic komatiites may have essentially undepleted or even slightly enriched geochemical characteristics<sup>11</sup>, but these are not a dominant group. The geochemical studies have also demonstrated that associated tholeiitic basalts in greenstone sequences have flat chondritic rare-earth patterns (Fig. 1), higher levels of incompatible elements and essentially 'undepleted' incompatible element ratios. They do not seem to be consanguineous with the depleted komatiitic lavas but have been derived from a different mantle source. Inhomogeneity in the Archaean mantle

**Fig. 1** Selected rare-earth patterns of depleted peridotitic komatiite (●); basaltic komatiite (★); and tholeiitic lavas (◆) from Australian, Rhodesian and North American greenstone belts. Data sources: Patterns 1, 2, 4, 5, 6, and 7 ref. 11; pattern 3, ref. 9; pattern 8, ref. 36. See also ref. 12.

is indicated<sup>11,12</sup>. The thermal problem of accounting for the high degree of melting of the more depleted mantle source is, however, exacerbated.

### Thermal aspects

Cawthorn's<sup>8</sup> modelling of the thermal budget of ascending mantle diapirs was based on estimated thermal parameters for pyrolite (undepleted mantle). We have repeated these calculations using a depleted, more refractory peridotite (which has had a basalt fraction extracted), and the results are shown in Table 1. A depleted, more magnesian peridotite not only has a higher 1-atm solidus temperature, but also has higher values than pyrolite for the latent heat of fusion and for the heat capacity. Estimates of these quantities have been made, and although the absolute values for the chosen parameters are uncertain, they do illustrate the relative difference in melting behaviour of a pyrolite and a more refractory mantle diapir. As emphasised by Cawthorn<sup>8</sup>, the latent heat of fusion exerts a large buffering effect on the degree of mantle melting. In fact, on the basis of recent thermochemical data<sup>13</sup>, the values used by Cawthorn for the latent heat of fusion may be rather low, accentuating the thermal problem of deriving komatiitic liquids from pyrolite diapirs. Similarly the value assumed for the latent heat of fusion of depleted mantle may be an underestimate, but was chosen only to be of the correct magnitude for direct comparison with Cawthorn's modelling.

For both models the mantle source region is assumed to be at the same initial temperature. Note, however, that the more magnesian depleted peridotite would be of lower density and significantly more buoyant than the pyrolite<sup>14</sup>, and may even begin to rise at temperatures below that of surrounding and overlying undepleted mantle<sup>14</sup>. Because the depleted peridotite solidus is 200 °C higher than that of pyrolite, a depleted peridotite diapir must undergo more adiabatic uprise in the solid state before intersecting the solidus than would a pyrolite diapir derived from the same depth. This has been accommodated in the modelling. Nevertheless, Table 1 shows that a refractory mantle model allows a higher 1-atm liquid temperature with a smaller degree of partial melting than does the pyrolite model; moreover, the Mg contents of the erupted liquids (calculated on the basis of the method of Hanson and Langmuir<sup>15</sup>) are also higher.

The depleted peridotite model therefore makes it possible to obtain the required liquidus temperature (~1,650 °C) by initiation of diapirism from shallower depths and with a smaller degree of partial melting than allowed by the pyrolite model. At the same time the depleted peridotite model has a built-in buoyancy factor able to initiate diapirism. Whether these features can be reconciled with a viable tectonic model for greenstone belts remains to be determined.

### Tectonic models

In seeking an acceptable tectonic model for greenstone belt formation it is necessary to account for the field, tectonic and chronological relationships of the various rock types, the geochemical characteristics of the lava sequences and associated plutons, and the thermal problems of komatiite generation. A wide variety of uniformitarian and non-uniformitarian models have been proposed<sup>1,16-22</sup>, although few consider the thermal constraints on the generation of komatiites. On the basis of heat flow modelling, Bickle<sup>23</sup> has suggested that subduction did occur in the Archaean, with sub-lithospheric heat flow of two or three times the present values and involving rapid production of lithospheric plates of comparable thickness to those at present. If subduction did take place, then the depleted mantle cap to the subducting lithosphere is an obvious source of depleted refractory mantle with the potential for diapiric uprise. Indeed Oxburgh and Parmentier<sup>24</sup> have suggested this as a probable mechanism for back-arc spreading and the formation of marginal basins. Here we extend this concept to link with earlier proposed marginal basin models for greenstone belts<sup>22</sup>.

The essence of the Oxburgh and Parmentier<sup>14,24</sup> model is that the depleted lithosphere with its basaltic capping sinks into the mantle until it heats up to or near the temperature of the surrounding mantle. At this point it segregates from the dense eclogite cap and rises diapirically because there is a significant

**Table 1** Ascending peridotite diapirs: % partial melting and temperatures and MgO contents of liquids

Initial <i>P</i> , <i>T</i> and depths of diapir			Pyrolite model <sup>8</sup>			Depleted peridotite model		
<i>P</i> (kbar)	Depth (km)	<i>T</i> (°C)	Final <i>T</i> (°C)	% Melt	% MgO*	Final <i>T</i> (°C)	% Melt	% MgO*
50	150	1,700	1,372	29	21	1,513	19	31
75	225	1,950	1,497	47	32	1,651	42	44
100	300	2,200	1,606	69	42	1,780	63	53

Parameters used in the modelling are:

Heat capacity of solid (cal g <sup>-1</sup> °C <sup>-1</sup> )	Pyrolite model <sup>8</sup>	Depleted peridotite model
Heat capacity of liquid (cal g <sup>-1</sup> °C <sup>-1</sup> )	0.30	0.35
Latent heat of fusion (cal g <sup>-1</sup> )	0.50	0.55
	100	120

Both models assume an adiabatic cooling rate of 1 °C kbar<sup>-1</sup>, with gravitational heat loss retained in the diapir of 0.4 cal g<sup>-1</sup> kbar<sup>-1</sup>. In the pyrolite model<sup>8</sup> the pyrolite solidus is taken to be at 1,200 °C at 1 atm, with d*T*/d*P* of 10 °C kbar<sup>-1</sup> with a nonlinear melting interval. The depleted peridotite model assumes a solidus at 1 atm, of 1,400 °C, again with d*T*/d*P* of 10 °C kbar<sup>-1</sup> but with a constant linear melting interval of 600 °C. Higher heat capacity and latent heat of fusion values based on mineral data in ref. 13.

\* Modelling of MgO abundances in liquids similar to that of Hanson and Langmuir<sup>15</sup>, using 1-atm distribution coefficients. Note quoted MgO values are in cation mol %. Pyrolite<sup>7</sup> has 48 cation mol % MgO; depleted peridotite assumed to have 53 cation mol % MgO (for reference, sample 49J from the Barberton belt<sup>1,5</sup> has 32% MgO equal to 42 cation mol %).

density difference ( $0.06\text{--}0.09\text{ g cm}^{-3}$ ) from the surrounding more Fe-rich undepleted mantle. The rising diapir will at some time intersect the refractory mantle solidus and thereafter undergo progressive fusion. The rising diapir may cause fusion of the normal mantle surrounding it (this is especially true where intrinsic buoyancy is a significant driving force in diapiric uprise<sup>25</sup>), allowing potential mixing of mantle sources or magmas. Thus the geochemistry of the erupted magmas could conceivably vary from 'depleted' to 'enriched' and need not directly reflect the composition of the diapir itself. The first magmas erupted would be peridotitic komatiite, but perturbation of the mantle by the diapir and dissipation of its remaining thermal energy would cause extensive basaltic volcanism characteristic of many greenstone sequences. Because this type of diapirism is closely linked to subduction and hence to zones of crustal generation, the general association of rock types would be similar to that proposed for the *rocas verdes* marginal basin model of Tarney *et al.*<sup>22</sup>.

The present model, however, allows considerable improvements to be made to the *rocas verdes* model, particularly towards explaining the lack of rifting of the lithosphere (and consequent spreading), the occurrence of multiple greenstone belts, repetitions of the volcanic cycle and the lack of modern equivalents of komatiitic lavas.

An important feature of the model is that the driving force is the intrinsic density contrast rather than a thermally dependent density contrast. The rate of diapiric uprise depends on both the size of the diapir and the viscosity of the surrounding mantle. High heat flow in the early Archaean<sup>23</sup> would mean that the mantle had a low viscosity, thereby enabling smaller diapirs to rise, with perhaps more than one pulse, leading to repeated volcanic sequences. However, the viscosity of the mantle will increase with time as the geothermal gradient falls as a consequence of crustal growth and the transfer of radioactive elements U, Th, K and Rb into the crust. Conversely the upper mantle becomes progressively more depleted and refractory (as evidenced by Nd and Sr isotope data<sup>26</sup>), lessening the density contrast with the subducting lithosphere. Thus only increasingly larger diapirs would be able to rise. The implication is that earlier greenstone belts might be smaller (for example, Barberton and Pilbara greenstones) with perhaps more repeated volcanic cycles, whereas later belts would be larger and more linear (for example, Superior Province, Yilgarn Block). Small diapirs might thin the crust and promote basin formation, but would not necessarily rupture the lithosphere. Eventually the density contrast would become too small and the viscosity too high to allow refractory mantle diapirs to migrate to higher levels. A corollary of this is that there may be no (or very rare) modern equivalents of komatiitic lavas. Alternatively, only very large diapirs would be able to rise; these, however, would rupture the lithosphere and generate seafloor spreading similar to that in modern back-arc marginal basins. It is interesting that high-magnesian (up to 18% MgO) lavas and dykes are known from several marginal basin ophiolite complexes, including the *rocas verdes* complex in southern Chile<sup>27</sup>.

The existence of multiple greenstone belts in younger Archaean provinces (for example, Superior Province, Yilgarn Block) poses problems for the conventional marginal basin model, bearing in mind the time constraints from these areas. Recent isotopic studies<sup>28</sup> have indicated that most of the Superior Province, including the greenstone belts, formed within a restricted time span of 100–200 Myr. This implies extremely rapid crustal generation and penecontemporaneous formation of the greenstone belts. Similar evidence exists from the Yilgarn Block<sup>29</sup>. One possibility is that the subduction zone migrates oceanwards as the newly generated crust accretes laterally and that a series of greenstone belts are formed in sequence, each generated by individual diapiric events. A modern parallel is the Mariana Arc system where a series of remnant arcs and intervening marginal basins have been formed since the mid-Tertiary as the active arc itself has moved eastwards<sup>30</sup>.

However, it is also possible that there is a small but significant hiatus between the generation of crust and formation of greenstone belts, and that the latter were all formed simultaneously. Cox<sup>31</sup>, for instance, has used the Oxburgh–Parmentier model<sup>24</sup> to account for the extensive early Mesozoic Karroo volcanism in southern Africa. He suggests that continued subduction of Pacific lithosphere along the western margin of Gondwanaland during the late Palaeozoic led to a substantial build-up of low-density refractory mantle in the 'back-arc' region beneath the continent, and that it was the eventual diapiric rise of this material into the more fertile mantle above that provided the thermal energy for the extensive Karroo-related volcanism. For this to be a feasible mechanism requires a fairly shallow subduction zone in order to carry depleted lithosphere well beneath the continent. Shallow subduction beneath the Andes is associated with voluminous calc-alkaline volcanism and plutonism, while equivalent subduction beneath the active basaltic island

Fig. 2 Schematic representation of back-arc diapirism in a region of rapid lateral crustal growth. Possible model for multiple greenstone belts is shown.

arcs and marginal basins of the Western Pacific is located along steeply inclined Benioff zones. Molnar and Atwater<sup>32</sup> have ascribed this difference to the age of the subducting lithosphere: older, cooler lithosphere in the Western Pacific sinking back steeply into the mantle while younger warmer lithosphere subsides more gently. The high heat flow in the Archaean coupled with rapid plate production and shorter convection cells would favour shallow subduction and, by analogy with the Andes, extensive crustal generation. The refractory subducted lithosphere could rise diapirically at several points under a continent to produce multiple (and ensialic) greenstone belts (Fig. 2). Provided they originated at depths in excess of 200 km, they could generate high-temperature lavas with the chemistry of peridotitic komatiites, as our calculations have shown.

Jordan<sup>33</sup> has argued, from seismic and heat-flow evidence, that the sub-continental lithosphere is composed of much more refractory mantle than the oceanic lithosphere, and that the thickness of this subcontinental 'tectosphere' may vary from as little as 100 km in young unstable regions to as much as 400 km beneath the older cratons. Oxburgh and Parmentier's model<sup>14</sup> provides a mechanism for the growth of this tectosphere through diapiric uprise of refractory Mg-rich lithosphere from the subducting slab. In this context greenstone belts could be considered as merely the surface expression of this process, where more active diapirs have managed to penetrate thin, immature, sub-continental tectosphere. Once a substantial tectosphere has developed beneath a continent it would, for reasons of density, viscosity and temperature, offer more resistance to penetration by such diapirs. Perhaps it is no coincidence then that most greenstone belts occur in regions which were geologically very young at the time the belts formed.

## Conclusions

This mechanism for the formation of Archaean ensialic greenstone belts may differ from that controlling the development of modern intra-oceanic marginal basins where, because of the more mature, cooler nature of the subducting lithosphere, the Benioff zone is steeply inclined. Toksöz and Bird<sup>34</sup> proposed that the down-dragging effect of the subducting slab induces convective circulation in the mantle wedge behind the volcanic arc, the broad upwardly convecting cell rupturing the lithosphere and causing back-arc spreading. Thus the effect may be different, but the strong link with subduction is present in both models. The original marginal basin model of Tarney *et al.*<sup>22</sup> was based on the Mesozoic ensialic *rocas verdes* complex in southern Chile where the amount of back-arc extension was very limited. When all aspects of greenstone belts are considered we feel that, when due allowance is made for the different Archaean thermal

regime and mantle structure, a marginal basin analogue is the model best able to accommodate the observed features of greenstone belts.

An important corollary is that extreme geothermal gradients implied for the Archaean mantle on the basis of the high liquidus temperatures of komatiitic lavas<sup>7</sup> are not necessarily correct. This is particularly important as far as eclogite stability in subduction zones is concerned because many Archaean crustal rocks have rare-earth element characteristics consistent with an origin through partial melting of eclogite<sup>35-37</sup>. Clearly also, caution must be exercised in deducing Archaean mantle compositions from high-magnesian komatiitic liquids; their compositions may merely reflect their local source regions.

# Efficient translation of prokaryotic mRNAs in a eukaryotic cell-free system requires addition of a cap structure

Bruce M. Paterson & Martin Rosenberg

Laboratories of Molecular Biology and Biochemistry, National Cancer Institute, National Institutes of Health, Bethesda, Maryland 20205

*In this and the accompanying paper we demonstrate that certain prokaryotic mRNAs, when modified at their 5'-termini with a cap structure, are translated in a eukaryotic cell-free protein synthesising system as efficiently as, or more efficiently than, eukaryotic mRNAs. Apparently, the prokaryotic mRNA contains all the information necessary for efficient recognition and initiation by eukaryotic translational components, except for the cap structure.*

MANY eukaryotic mRNAs are modified at their 5'-termini with a cap structure consisting of 7-methylguanosine in 5'-linkage with the first encoded base of an mRNA<sup>1-3</sup>. *In vitro* translation experiments with various eukaryotic cell-free protein synthesising systems indicate that the presence of the cap moiety is required for efficient translation of these messages<sup>4-18</sup>. Although the degree of cap-dependent translation varies among different mRNAs and depends on the *in vitro* translation system used<sup>8</sup> as well as on the particular conditions in which the translation reactions are carried out<sup>19,20</sup>, the results clearly suggest an important physiological role for the cap structure in the expression of these mRNAs.

Various prokaryotic mRNAs (for example, RNA phage, T7 'early' RNA) have been translated in both mammalian and wheat-germ cell-free systems to produce accurate and functional protein products<sup>21-27</sup>. However, in these experiments it was necessary to use relatively high concentrations of the prokaryotic mRNAs to obtain detectable synthesis of the protein products. The translational efficiencies of these prokaryotic mRNAs were significantly lower than the corresponding efficiencies exhibited by equivalent amounts of most eukaryotic mRNAs (as judged by the amino acid incorporation per mol of mRNA added to the translation reaction). The prokaryotic mRNAs were, in fact, translated at levels equivalent to those obtained with eukaryotic mRNAs lacking cap structures.

In this and the following article<sup>28</sup> we examine the translation of several well-defined prokaryotic mRNAs in a wheat-germ cell-free system and, in particular, the effect of the enzymatic addition of a cap moiety on the translational efficiencies of these mRNAs. Our results indicate that these messages can be translated at relatively high efficiency in the wheat-germ extract and, analogous to the situation described for many eukaryotic mRNAs, this efficient translation is absolutely dependent on modification of the prokaryotic transcript with the cap structure. For each case examined, the capped prokaryotic mRNA was

found to translate as efficiently as, or more efficiently than, the equivalent amount (per mol) of capped rabbit haemoglobin (Hb) mRNA. Moreover, the cap-dependent translation exhibited by these mRNAs has allowed: (1) detection of an endogenous capping activity present in wheat-germ extracts, (2) comparison of the relative translational efficiencies exhibited by an mRNA encoding the same gene when located at different positions within a transcript, (3) demonstration that an mRNA which atypically initiates with a 5'-pyrimidine triphosphate can be cap-modified and translated, and (4) comparison of the translational efficiencies exhibited by two mRNAs which encode the same gene product but differ in their 5'-non-coding regions.

### Synthesis of the $\lambda$ *cro* gene product

Transcription of phage  $\lambda$  DNA with purified *Escherichia coli* RNA polymerase yields four major, well characterised RNA transcripts (Fig. 1)<sup>29-31</sup>. Two of these transcripts are relatively high molecular weight (MW) (>16S) polycistronic mRNAs which are known to code for a variety of phage functions. They initiate from the major early promoters of phage  $\lambda$ ,  $p_L$  and  $p_R$ , and extend leftward and rightward, respectively, from the  $\lambda$  immunity region (Fig. 1). In addition, two smaller transcripts are synthesised (4S and 6S RNAs), but these do not code for viral proteins. If the *in vitro* transcription reaction is carried out in the presence of the transcription termination protein factor, *rho*, then the  $p_L$  and  $p_R$  initiated mRNAs are terminated early at sites  $t_L$  and  $t_R$ , respectively, resulting in the production of discrete lower MW monocistronic mRNAs. A 12S RNA which encodes the  $\lambda N$  gene function is obtained from the left, and an 8S mRNA which encodes the  $\lambda$  *cro* gene product results from the right (Fig. 1)<sup>29-32</sup>.

**Fig. 1** Partial genetic map of bacteriophage  $\lambda$  showing the locations and relative sizes of the major RNA transcripts and some of the genes which they encode. In this study  $\lambda^+$  is actually  $\lambda b2$ , a derivative deleted for certain non-essential genes, thereby simplifying the *in vitro* RNA transcription pattern<sup>29</sup>. *c17* represents a small DNA insertion which occurs within the intercistronic boundary between the genes *cro* and *cII* and creates a new RNA polymerase promoter site (*p*) for RNA transcription<sup>32,44,45</sup>. The region of substitution of the entire galactose operon of *E. coli* (*gal* ETK) which occurs in the  $\lambda$  transducing phage,  $\lambda$  *pagal*8, is also indicated. All other designations are explained in the text.

RNA was prepared *in vitro* from a *rho* transcription reaction using  $\lambda$  DNA as template and then added to a wheat-germ cell-free translation system (Fig. 2). Addition of total RNA (that is, 4S, 6S, 8S and 12S RNA species) stimulated incorporation of <sup>35</sup>S-methionine into a single prominent polypeptide of ~7,500 daltons (Fig. 2-1). This protein was initially identified as the  $\lambda$  *cro* gene product by carrying out analogous translations on transcripts prepared identically from several well characterised  $\lambda$  mutants. The first,  $\lambda$  *x13*, carries a point mutation in  $p_R$  and is unable to initiate transcription of the 8S *cro* gene mRNA<sup>29</sup>. The second,  $\lambda$  *Δcro*, is deleted for the *cro* gene function. Although other RNAs are transcribed normally from the two mutants, these RNAs did not direct synthesis of the 7,500-dalton polypeptide (Fig. 2-2, 7). In contrast, translation of total RNA (all four species) prepared from a third mutant,  $\lambda$  *NN*<sup>-</sup>, which carries a double amber mutation in the *N* gene product (encoded by the 12S mRNA species)<sup>33</sup> did produce the 7,500-dalton polypeptide (Fig. 2-3). Thus, production of this polypeptide is apparently solely dependent on the presence of the 8S *cro* mRNA species. Identification was confirmed by preparing transcripts from a purified DNA restriction fragment which spanned

**Fig. 2** Autoradiograph of a 12.5% SDS-polyacrylamide gel analysis of the <sup>35</sup>S-methionine-labelled cell-free products synthesised in wheat-germ extracts in response to RNA transcribed *in vitro* from the indicated  $\lambda$  phage DNAs (see text for description of the various  $\lambda$  derivatives). Wheat-germ translations were carried out (as described below) in 50- $\mu$ l reactions using the following components: (1) ~1.0 pmol of 8S *cro* mRNA contained in ~0.8  $\mu$ g total RNA prepared from  $\lambda^+$  DNA; (2) ~0.8  $\mu$ g total RNA prepared from  $\lambda$  *x13* DNA; (3) 0.8  $\mu$ g total RNA prepared from  $\lambda$  *NN*<sup>-</sup> DNA; (4) no added RNA (endogenous); (5) ~1.2 pmol *cro* mRNA contained in ~150 ng total RNA prepared from a purified  $\lambda$  DNA restriction fragment (see below and text); (6) ~0.4  $\mu$ g total RNA prepared from  $\lambda$  *imm434* DNA; (7) ~0.4  $\mu$ g total RNA prepared from a  $\lambda$  derivative which is deleted for the *cro* gene,  $\lambda$  *bio7-20nutL44croΔ2*; (8) same as (1); (9) same as (4). RNA transcriptions were carried out as previously described<sup>31,32</sup> with the following modifications: reaction volume (0.5 ml), template DNA (2.5 pmol ml<sup>-1</sup>), *E. coli* RNA polymerase (40  $\mu$ g ml<sup>-1</sup>), purified *rho* factor (10  $\mu$ g ml<sup>-1</sup>). RNA synthesis was monitored and quantitated by incorporating [ $\alpha$ -<sup>32</sup>P]ATP (specific activity 10 mCi mmol<sup>-1</sup>) into a separate aliquot of the transcription reaction. Reactions were terminated by the addition of pancreatic DNase (25  $\mu$ g). After an additional 5 min incubation at 20 °C, the reaction mixture was made 0.1% in SDS, extracted with phenol, and precipitated twice with 2.5 volume of ethanol at -20 °C. The pellet was washed with 95% ethanol, dried and dissolved in H<sub>2</sub>O. For certain reactions (1, 5 and 8) the relative yields of 4S, 6S, 8S and 12S RNA species were determined by analysing the aliquot of <sup>32</sup>P-labelled RNA on a 3.5% polyacrylamide slab gel containing 8.0 M urea<sup>32,33,51</sup>. Wheat-germ cell-free translations were carried out essentially as described<sup>46</sup>. Reaction mixtures (50  $\mu$ l) contained micrococcal nuclease-treated wheat-germ extract (10  $\mu$ l), SAM (5  $\mu$ M), ATP (1 mM), GTP (0.4 mM), magnesium acetate (2.0 mM), spermidine (600  $\mu$ M, free base), creatine phosphate (8 mM), creatine phosphokinase (8  $\mu$ g ml<sup>-1</sup>; Sigma, 155 U per mg), KCl (85 mM), HEPES (25 mM, pH 7.6), amino acids minus methionine (25 mmol l<sup>-1</sup>, dithiothreitol (2 mM), <sup>35</sup>S-methionine (10-15  $\mu$ Ci at 400-800 Ci mmol<sup>-1</sup>, Amersham), and the indicated amounts of RNA. Protein synthesis was monitored by hot trichloroacetic acid precipitation as previously described<sup>46</sup>. Preparation and running of the samples on the 12.5% SDS-polyacrylamide slab gel have also been described<sup>46</sup>. After electrophoresis the gel was fluorographed for ~12 h at -70 °C (ref. 46). All values given represent final concentrations in the reaction mixture. The DNA restriction fragment used to prepare *cro* mRNA for translation reaction (5) was obtained from phage  $\lambda$  *r32*, a derivative which contains an IS2 insertion element within the *cro*-*cII* intercistronic boundary<sup>32</sup>. Restriction of this DNA with *Hind*III results in productions of a readily obtainable 1,600-base pair DNA fragment which spans the  $p_R$ -*cro* region (K. McKenney, unpublished data).

the *cro* cistron and contained only the  $p_R$  initiation site for RNA transcription. Translation of this RNA, which consists almost exclusively of the 8S *cro* mRNA, again results in production of the major 7,500-dalton polypeptide (Fig. 2-5).

Authentic *cro* protein has been obtained *in vivo* from  $\lambda$ -infected cells and is known to have a MW of 7,500 (ref. 34). Moreover, the nucleotide sequence of the region of the  $\lambda$  genome which encodes the 8S *cro* mRNA has been deter-

mined<sup>35</sup>, as has the amino acid sequence of the purified protein<sup>36</sup>. These data indicate that the 7,500-dalton *cro* polypeptide is a primary translation product and that the *cro* mRNA contains only one possible reading frame of codon triplets consistent with a protein of this size. Apparently, the 7,500-dalton protein being synthesised in the wheat-germ extract is the  $\lambda$ *cro* gene product. More recent studies (C. Queen, B.M.P. and M.R., unpublished results) indicate that translation of this same  $\lambda$  transcript in an *E. coli* S30 translation system results in the synthesis of the identical protein product.

RNA transcribed from the  $\lambda$ x13 phage DNA template directed synthesis of a minor polypeptide of slightly higher MW than the  $\lambda$ *cro* protein (Fig. 2-2). This product did not seem to result from translation of any of the major  $\lambda$  mRNA species, but rather was accounted for by the following observations. The  $\lambda$ x13 phage is a replication-defective mutant and requires a helper phage for its growth. The helper phage (in this case the hetero-immune phage  $\lambda$ imm434) is subsequently separated from  $\lambda$ x13 by CsCl gradient centrifugation, although some cross-contamination between the two phages usually occurs. The  $\lambda$ 434 phage has an entirely different and somewhat larger *cro* gene than  $\lambda^+$  (ref. 37). Transcripts were prepared from purified  $\lambda$ 434 phage DNA and translated in the wheat-germ system (Fig. 2-6). Their translation resulted in the production of a single major polypeptide which had a gel mobility identical to the minor product observed from translation of the  $\lambda$ x13 mRNA (compare Fig. 2-2, 6). Apparently, the wheat-germ extract was able to translate the small amount of  $\lambda$ 434 *cro* mRNA which was transcribed with and contaminated the  $\lambda$ x13 mRNA preparation.

We emphasise that although the *cro* genes of  $\lambda^+$  and  $\lambda$ 434 are functional analogues, the nucleotide sequences of these two genes show little, if any, homology even in those regions involved in ribosome recognition and initiation of protein synthesis (ref. 37 and V. Pirrotta, unpublished data). Thus, the two *cro* genes actually represent independent examples of prokaryotic sequences which are being recognised and translated by the wheat-germ components.

### Synthesis of *cro* polypeptide is cap dependent

The cap structure is required for efficient translation of reovirus RNA<sup>4,38</sup>. This was demonstrated by monitoring the relative translational efficiencies exhibited by reovirus RNA which had been prepared *in vitro* in the presence or absence of *S*-adenosylmethionine (SAM). SAM acts as a methyl donor in the capping reaction and is required for the formation of a functional cap structure<sup>2</sup>. The viral RNA transcribed in the presence of SAM exhibited a significantly higher translational efficiency than RNA synthesised without added SAM. Moreover, it was observed that addition of *S*-adenosylhomocysteine (SAH) to the reovirus *in vitro* transcription system resulted in a sharp reduction in the ability to translate the reovirus RNA<sup>2,38</sup>. SAH is an analogue of SAM which competitively inhibits formation of the cap structure on the reovirus RNA.

We have used similar criteria to determine the extent of cap-dependent translation of  $\lambda$ *cro* mRNA in the wheat-germ cell-free system. As before, *cro* mRNA was prepared *in vitro* as

**Fig. 3** Composite autoradiograph of an SDS-polyacrylamide gel analysis (as in Fig. 2) showing the effects of the indicated manipulations on the cell-free synthesis in wheat-germ extracts of the  $\lambda$ *cro* polypeptide (1-13) and haemoglobin (Hb) protein (14-19).  $\lambda^+$  RNA was prepared *in vitro* (as described in Fig. 2) and identical aliquots of RNA (~0.5 pmol of 8S *cro* mRNA contained in ~0.4  $\mu$ g total RNA) were used for each translation reaction. Translations were carried out (as described in Fig. 2) except that *S*-adenosylmethionine was added only where indicated) in 50- $\mu$ l reactions using the following components: (1) no added RNA (endogenous); (2)  $\lambda$  RNA only; (3)  $\lambda$  RNA + *S*-adenosylhomocysteine (SAH, 500  $\mu$ M); (4)  $\lambda$  RNA + *S*-adenosylmethionine (SAM, 5  $\mu$ M); (5)  $\lambda$  RNA + m<sup>7</sup>GpppA (500  $\mu$ M); (6)  $\lambda$  RNA, which was initially cap-modified using the purified vaccinia capping enzymes (described below); (7) same as (1); (8) same as (6); (9) cap-modified  $\lambda$  RNA (as in 6) + SAH (500  $\mu$ M); (10) cap-modified  $\lambda$  RNA (as in 6) + m<sup>7</sup>GpppA (500  $\mu$ M); (11)  $\lambda$  RNA, which was initially treated with bacterial alkaline phosphatase (BAP, see below) + SAM (5  $\mu$ M); (12) cap-modified  $\lambda$  RNA (as in 6 and 8); (13) cap-modified  $\lambda$  RNA (as in 6), which was initially treated with BAP (as in 11); (14) same as (1) and (7); (15) Hb mRNA only (0.6 pmol); (16) Hb mRNA (0.6 pmol) + SAM (5  $\mu$ M); (17) Hb mRNA only (3.0 pmol); (18) Hb mRNA (3.0 pmol) + SAH (500  $\mu$ M); (19) Hb mRNA (3.0 pmol) + m<sup>7</sup>GpppA (500  $\mu$ M). RNA was cap-modified before translation using the purified vaccinia capping enzymes<sup>40</sup>. Reaction mixtures (10-40  $\mu$ l) contained Tris-HCl (50 mM, pH 7.5), MgCl<sub>2</sub> (1 mM), GTP (1-2 mM), dithiothreitol (5 mM), SAM (0.1 mM), RNA (~0.4  $\mu$ g) and enzyme extract<sup>40</sup>. After 20 min incubation at 37 °C, the reaction mixture was phenol extracted and precipitated twice with ethanol at -20 °C. The pellet was washed with 95% ethanol, dried, dissolved in H<sub>2</sub>O and then used directly for translation. Bacterial alkaline phosphatase treatment of RNA was carried out in reaction mixtures (0.1 ml) containing Tris-HCl (5 mM, pH 0.8), MgCl<sub>2</sub> (5 mM), RNA (0.4-1.0  $\mu$ g) and BAP (1.0  $\mu$ g, Sigma). After 20 min incubation at 37 °C, EDTA (10 mM) was added and the reaction mixture was phenol extracted and precipitated twice with ethanol at -20 °C. The pellet was washed with 95% ethanol, dried, dissolved in H<sub>2</sub>O and then used directly in the translation reaction.

a primary 8S mRNA and subsequently translated in a standard wheat-germ translation reaction (Fig. 3). In this case, however, the translation reactions were carried out in the presence and absence of SAM and SAH. Addition of SAM resulted in markedly enhanced synthesis of the cro polypeptide (about threefold, compare Fig. 3-2, 4). In contrast, SAH addition (Fig. 3-3) completely and selectively abolished the synthesis of cro. These data indicate that translation of cro in the wheat-germ extract depends on an endogenous SAM-mediated (SAH-inhibited) methylation reaction. Analogous to the situation described above for reovirus RNA translation, this methylase activity is presumably that which is associated with the formation of a functional cap structure.

The observed effects are specific for an mRNA which requires endogenous cap modification for its translation. Similar addition of either SAM or SAH to translation reactions containing purified Hb mRNA had no effect on the synthesis of Hb protein (Fig. 3-15-18). As Hb mRNA already contains a 5'-cap structure, its translation is independent of the effects of SAM and SAH on the wheat-germ methylation activity. This is also true for the products which result from translation of the endogenous wheat-germ mRNAs present in the various reactions (compare Fig. 3-1-4). These RNAs, like Hb, already contain a cap structure and thus serve as direct internal controls in the translation reactions. Thus, the specificity of the effects observed with cro mRNA indicates that an endogenous capping activity present in the wheat-germ extract can appropriately modify the 5'-triphosphate terminus of the prokaryotic transcript and lead to its enhanced ability to be translated in the cell-free system. The presence of an enzymatic capping activity in the wheat-germ extract was recently confirmed (B. Moss, personal communication).

We have also directly demonstrated cap-dependent translation of the cro mRNA using enzymatic capping activity from vaccinia virions<sup>39,40</sup>. The enzymes were used to cap-modify the *in vitro* synthesised  $\lambda$  mRNA before translation in the wheat-germ system. The vaccinia enzymes add a cap structure to RNAs which contain either a 5'-di- or triphosphate terminus<sup>40</sup>. Capping reactions were initially carried out with [ $\alpha$ -<sup>32</sup>P]GTP so as to monitor and quantitate the extent of cap modification of the  $\lambda$  transcripts (see Fig. 4 legend). Analysis of these enzymatically capped RNAs by polyacrylamide gel electrophoresis indicated that each of the  $\lambda$  transcripts had incorporated <sup>32</sup>P label (not shown). More importantly, enzymatic digestion of this RNA with T<sub>1</sub> RNase and subsequent two-dimensional fingerprint analysis of the products demonstrated that the <sup>32</sup>P label was specifically transferred to four oligonucleotides which had mobilities consistent with the cap derivatives of the known 5'-terminal oligonucleotides of each of the four  $\lambda$  transcripts (Fig. 4). The specific activity of the products indicated that ~60% of the cro mRNA was cap-modified; enzymatic addition of the cap structure to the other three transcripts ranged between 40% and 60%.

$\lambda^+$  RNA, prepared *in vitro* and capped with the vaccinia enzyme, was added to the wheat-germ cell-free translation system. Translation of this RNA resulted in a >10-fold increase in production of cro protein as compared with translation of an identical amount of untreated transcript (compare Fig. 3-6, 2). Thus, direct cap modification of ~60% of the input prokaryotic message resulted in a dramatic increase in its ability to be translated in this eukaryotic system. Moreover, these pre-capped transcripts now continued to direct the synthesis of cro protein even in the presence of SAH (Fig. 3-9), analogous to the translation of Hb mRNA (Fig. 3-18). Cap modification with the vaccinia enzymes has eliminated the need for endogenous cap formation during the translation reaction.

The requirement for the integrity of the 5'-triphosphate group on the cro mRNA primary transcript was also demonstrated. Removal of the terminal phosphate residues by initial treatment of the RNA with bacterial alkaline phosphatase (BAP), followed by addition of this RNA to a translation reaction (+SAM) abolished synthesis of the cro polypeptide (Fig. 3-11).

**Fig. 4** Autoradiograph of a two-dimensional fingerprint (prepared as previously described)<sup>31,47,48</sup> showing the 5'-terminal RNase T<sub>1</sub> oligonucleotide products resulting from cap modification of the four  $\lambda$  RNA transcripts. Unlabelled  $\lambda^+$  RNA was prepared *in vitro* (as described in Fig. 2) and then cap-modified using the vaccinia enzymes, as described in Fig. 3 except that SAM was omitted from the reaction and [ $\alpha$ -<sup>32</sup>P]GTP (1-2 mCi, specific activity ~100 mCi  $\mu$ mol<sup>-1</sup>) was used to label specifically (by the cap-moiety) the 5'-triphosphate termini of the unlabelled transcripts. Horizontal dimension: electrophoresis on Cellolog in 8.0 M urea at pH 3.5. Vertical dimension: ascending thin-layer homochromatography on plates of DEAE-cellulose using homo-solvent B (refs 47, 48). The stippled circles show the approximate relative positions and nucleotide sequences of the unmodified 5'-terminal oligonucleotide products which are known to result from T<sub>1</sub> RNase digestion of the four  $\lambda$  transcripts (refs 49, 50, and unpublished data).

However, identical BAP treatment of  $\lambda$  RNA which had been pre-capped with the vaccinia enzymes had no effect on its ability to be translated (Fig. 3-13). Thus, the 5'-terminal triphosphate group was protected from phosphatase activity by the presence of the added cap structure.

Further evidence for the cap dependence of cro protein translation was obtained from experiments using m<sup>7</sup>G(5')pppA, a cap analogue which will inhibit the translation of capped mRNA<sup>14,20,41</sup>. Cap analogues seem to have little effect on cap-independent translation<sup>21</sup>. Addition of m<sup>7</sup>G(5')pppA to the translation reactions abolished the synthesis of both the Hb and cro polypeptides (Fig. 3-5, 19), as well as the synthesis of endogenous wheat-germ proteins (that is, background; compare Fig. 3-1, 5). Identical results were obtained whether cap modification occurred during the translation reaction (in response to added SAM, Fig. 3-5) or before translation using the vaccinia enzymes (Fig. 3-10).

Experiments similar to those described for the  $\lambda$ cro gene product were also carried out with the  $\lambda$ imm434 cro gene. Essentially identical results were obtained (data not shown). Again, we emphasise that these two prokaryotic mRNAs are quite different in primary structure, but exhibit similar cap dependence. In contrast to the results obtained with cro protein,

we were unable to detect synthesis of the  $\lambda$ N protein, the gene product encoded by the 12S mRNA species. Although cap modification of this RNA was achieved using the vaccinia capping enzymes (Fig. 4), no obvious translation product was observed. Structural characterisation of the 5'-terminal region of the 12S RNA suggests that the translation start point for the N protein may be relatively far (>200 nucleotide residues) from the 5'-triphosphate end (ref. 41 and K. McKenney, unpublished data). In addition, the 5'-non-coding region of this transcript is

known to be processed *in vivo* into several discrete RNA fragments<sup>43</sup>. Perhaps the length and/or structure of the 12S RNA leader region does not allow proper interaction between the 5'-terminal cap modification and the site for ribosome recognition and translation initiation of the N protein.

We thank Catherine Brady for technical assistance, Jean Regan for typing the manuscript, and Ray Steinberg for help with the illustrations.  $\lambda\Delta$ cro was obtained from J. Salstrom, enzyme extract from B. Moss, and Hb mRNA from B. Roberts.

# Efficient cap-dependent translation of polycistronic prokaryotic mRNAs is restricted to the first gene in the operon

Martin Rosenberg & Bruce M. Paterson

Laboratories of Molecular Biology and Biochemistry, National Cancer Institute, National Institutes of Health, Bethesda, Maryland 20205

*Certain polycistronic prokaryotic mRNAs, when modified at their 5'-termini with a cap structure, are translated as efficiently as, or more efficiently than eukaryotic mRNAs in a eukaryotic cell-free protein synthesising system. However, in this case efficient cap-dependent translation is apparently restricted to the 5'-proximal coding sequence. Moreover, certain translational regulatory signals potentially used by these prokaryotic mRNAs to regulate their levels of expression seem to be recognised by the eukaryotic translational components. The evolutionary significance and practical implications of these results are discussed.*

IN the previous article<sup>1</sup> we demonstrated the cap-dependent translation of the monocistronic 8S  $\lambda$ cro mRNA in a wheat-germ cell-free protein synthesising system. These studies also allowed the detection of an endogenous capping activity present in the wheat-germ extract. Here, we extend these observations to other prokaryotic transcripts and, in particular, examine the cap-dependent translation of certain polycistronic mRNAs.

## Cap dependence in a polycistronic operon

Transcription of  $\lambda$  DNA in the absence of the protein termination factor *rho* results in the production of two high molecular weight (MW) polycistronic transcripts which are derived from the elongation of the 8S and 12S mRNAs<sup>2-5</sup> (see accompanying paper, Fig. 1). The *cro* gene now occurs at the 5'-end of a polycistronic transcript which is derived from the right operon of  $\lambda$  and encodes several other  $\lambda$  gene products. Translation of these high molecular weight mRNAs in the wheat-germ system again resulted in the synthesis of *cro* protein as the only major translation product (Fig. 1-1). Efficient translation of *cro* from the polycistronic message exhibited the identical dependence on cap modification to that observed for the 8S monocistronic mRNA (data not shown). The inability to detect protein synthesis from any of the cistrons located internally on the transcripts suggests that protein initiation sites positioned 'too far' from the cap structure may not be efficiently recognised by the eukaryotic translational components. Thus, it may be the relative proximity of the translation start site to the cap-modifiable 5'-triphosphate end of the transcript that is important for efficient *cro* protein translation. The following observations strongly support this contention.

The *cII* gene of  $\lambda$  comprises the second cistron of the  $p_R$  promoted major rightward operon (see accompanying paper, Fig. 1). This gene is located distal to the *cro* gene and separated from it by an intercistronic regulatory region of ~120 base pairs<sup>5</sup>. A well characterised  $\lambda$  mutant,  $\lambda c17$ , contains a small DNA insertion within the intercistronic boundary between *cro* and *cII*, immediately preceding the presumptive ribosome binding region of *cII* (refs 5–7). This insertion creates a new promoter site for RNA polymerase and results in the transcription and functional expression of the *cII* coding region<sup>7</sup>. Transcription from this *c17* promoter initiates atypically with a pyrimidine triphosphate (CTP) and this 5'-triphosphate end occurs only 18 residues from the presumptive AUG initiation codon for *cII* (Fig. 3)<sup>5</sup>. Thus, *in vitro* transcription of the  $\lambda c17$  DNA template gives rise to one additional *c17* promoted transcript, which places the *cII* coding region in proximity to a new, cap-modifiable 5'-triphosphate end.

RNA transcripts were prepared *in vitro* using the  $\lambda c17$  DNA template and subsequently translated in the wheat-germ cell-free system (Fig. 1). In contrast to the results obtained using the  $\lambda^+$  DNA template, three major protein products were now obtained: the expected 7,500-dalton *cro* polypeptide and two additional proteins of ~12,000 and 14,000 daltons (Fig. 1–2). The single additional *c17* promoted transcript seemed to be responsible for the synthesis of both new polypeptides. This was confirmed when the same two protein products were obtained in

translation reactions carried out with RNA prepared from a purified DNA restriction fragment of  $\lambda c17$  (data not shown). This DNA fragment contains the *c17* promoter and the entire *cII* coding region, but lacks the major  $p_L$  and  $p_R$  promoters of  $\lambda$  (ref. 5).

Translation of both new polypeptides, as well as the *cro* protein, was dependent on cap modification of the  $\lambda c17$  mRNA. As with the translation of *cro* mRNA, synthesis of the two new polypeptides was markedly enhanced by S-adenosylmethionine (SAM) addition (Fig. 1–3) and sharply inhibited by S-adenosylhomocysteine (SAH) addition (Fig. 1–4) to the wheat-germ translation reaction. Moreover, cap modification before translation using the purified vaccinia enzymes again dramatically increased the production of both polypeptides (not shown).

Initial characterisation of the two new polypeptides was achieved by directing translation reactions with mRNA prepared from a derivative of  $\lambda c17$  which carries an amber point mutation within the *cII* gene ( $\lambda c17IIamber41$ ). Translation of the RNA surprisingly resulted in gel electrophoretic mobility shifts for both the 12,000 and 14,000 dalton polypeptides (Fig. 1–6). No change was detected for the *cro* polypeptide. As the amber mutation results from a single base-pair change<sup>9</sup>, both polypeptides must not only be derived from the *cII* coding region, but must also be translated in the same reading frame of codon triplets. Preliminary <sup>35</sup>S-methionine tryptic peptide mapping of these two *cII* proteins indicates that they do share

**Fig. 1** Composite autoradiograph of a gel analysis (as described in Fig. 2 of the accompanying paper) showing the <sup>35</sup>S-labelled products synthesised in wheat-germ extracts in response to RNA transcribed *in vitro* (see accompanying paper, Fig. 2) from various  $\lambda$  phage DNAs (see text for description of each  $\lambda$  derivative). Wheat-germ cell-free translations were carried out (as described in Fig. 3 of the accompanying paper) in 50- $\mu$ l reactions using the following components: (1)  $\lambda^+$  RNA (as in Fig. 3 of the accompanying paper except that *rho* factor was omitted from the transcription reaction); (2)  $\lambda c17$  RNA (containing ~0.6 pmol 8S *cro* mRNA in 0.5  $\mu$ g total RNA); (3)  $\lambda c17$  RNA (as in 2) + SAM (5  $\mu$ M); (4)  $\lambda c17$  RNA (as in 2) + SAH (500  $\mu$ M); (5) same as (3); (6)  $\lambda c17IIamber$  RNA (~0.4  $\mu$ g) + SAM (5  $\mu$ M); (7) no added RNA (endogenous); (8)  $\lambda ggal8$  RNA, prepared in the absence of *rho* factor; (9)  $\lambda ggal8$  RNA, prepared as in (8) except that CRP (40  $\mu$ g ml<sup>-1</sup>) and cyclic AMP (0.3 mM) were added to the transcription reaction, +SAM (5  $\mu$ M); (10) same RNA as in (9) + SAH (500  $\mu$ M); (11) same as (9); (12)  $\lambda ggalochreb4$  RNA, prepared with CRP (40  $\mu$ g ml<sup>-1</sup>) and cyclic AMP (0.3 mM) added to the transcription reaction; (13) same as (7); (14) same as (8); (15)  $\lambda ggal8$  RNA, prepared as in (8) and (14) except that glycerol (20%) was added to the transcription reaction; (16) same RNA as in (15) + SAH (500  $\mu$ M). All values given are final concentrations in the reaction mix. The two presumptive *cII* fragments indicated in (5) and (6) have not been shown to be derived from the *cIIamber41* mutation. The differences in relative intensity observed for the two *cII* fragments presumably result from the corresponding changes which occur in their respective methionine content. The minor band which remains at the *cIIa* position is an endogenous product (compare with Fig. 2-4 or 3-1 of the accompanying paper). The amounts of *gal E* specific mRNA added to translation reactions (8)–(16) were not determined; however, each translation reaction was directed with an identical aliquot of RNA obtained from each of the  $\lambda ggal8$  transcription reactions. Furthermore, these aliquots of RNA were estimated to approximate to those used in translation reactions 1–6.

common peptides and that the smaller protein consists mainly of a subset of the tryptic products contained in the larger protein (unpublished results). Moreover, the amber mutation seems to have resulted in a similar reduction in MW for each polypeptide (Fig. 1 see legend). If this is correct, then both the cII polypeptides must have the same (or nearly identical) carboxy termini and differ only (or predominantly) at their amino-terminal ends (by ~20–25 amino acid residues, Fig. 3).

An authentic 14,000 MW protein, which is derived from the cII coding region, has been identified from  $\lambda$ -infected cells<sup>10</sup>. The DNA sequence of the cII coding region predicts a protein of this MW<sup>9</sup>. Thus, the larger of the two cII proteins (cIIa, Fig. 1) synthesised in wheat-germ in response to the capped c17 transcript is likely to be this protein. The smaller 12,000-dalton polypeptide (cIIb) probably initiates translation 20–25 codon positions to the right of this site. The apparent size reduction resulting from chain termination observed for the two proteins would then be entirely consistent with the known nucleotide position of the amber mutation in the cII gene. Furthermore, a second AUG codon does occur at amino acid position 23 of the cIIa protein (position 84–87 in the c17 mRNA, Fig. 3). This AUG might serve as the initiator codon of cIIb. Ribosome binding studies support this contention (M.R. and B.M.P., in preparation). In separate reactions, translation components from either wheat-germ or *Escherichia coli* were used to form stable translation initiation complexes with the purified c17-promoted transcript. Both the 60S prokaryotic ribosome and the 70S eukaryotic ribosome were found to bind specifically and protect (from ribonuclease digestion) two separate and identical regions of this RNA. Each protected site spanned about 30–40 nucleotide residues and centred around one of the appropriate AUG codons. It is not known whether these two overlapping sites for protein synthesis have any functional significance for the bacteriophage. However, recent studies (C. Queen, B.M.P. and M.R.) indicate that two proteins of identical electrophoretic mobilities to those made in wheat-germ can be synthesised in an *E. coli* S30 translation system using the same *in vitro* prepared  $\lambda$  transcripts. Thus, the wheat-germ translational components may be recognising a translational regulatory mechanism used by  $\lambda$  to produce two different polypeptides from the same coding region.

Regardless of the possible functional implications of the two overlapping cII proteins, their translational in the wheat-germ system required cap modification of the c17-initiated mRNA. As we described earlier, the sequences encoding the cII regulatory region also occur on the  $p_R$ -initiated polycistronic transcript which was synthesised from the  $\lambda^+$  DNA template. In this case, cII is the second cistron of the operon, located ~330 nucleotide residues away from the cap-modified 5'-end. Translation of the  $p_R$ -promoted mRNA did not result in detectable synthesis of either cII protein (Fig. 1-1). Only on introduction of a new transcription start site (through the c17 promoter), which placed a cap-modifiable 5'-triphosphate terminus in the proximity of the cII coding region, was efficient translation of cII obtained. Moreover, cap modification of the initiating pyrimidine nucleotide, CTP, of the c17 mRNA resulted in efficient translation from two different sites, respectively, 18 and 84 residues from the cap structure. The larger protein (initiated closer to the cap) was always obtained in somewhat higher yield (~60%) than the smaller cII protein (~40%, normalised for methionine content). We do not know whether the two start sites represent functionally independent regions for translation initiation or whether their function is related. The mechanism which leads to the cap-dependent synthesis of the two cII proteins is being studied.

### Cap-dependent *gal E* translation

The *gal* operon of *E. coli* consists of three structural genes, *E* (epimerase), *T* (transferase) and *K* (kinase), which are transcribed into a single polycistronic mRNA from a promoter region which has been well characterised<sup>11–13</sup> (see accompanying paper, Fig. 1). *In vitro*, transcription of *gal* DNA can occur

from either of two distinct sites which are known to be 5 base pairs apart within the *gal* regulatory region (start sites *S*<sub>1</sub> and *S*<sub>2</sub>, Fig. 3)<sup>14</sup>. Transcription from start site *S*<sub>1</sub> requires the presence of cyclic AMP receptor protein (CRP) and cyclic AMP in the transcription reaction<sup>14</sup>. In these conditions, no transcription initiates from start site *S*<sub>2</sub>. In the absence of CRP and cyclic AMP, *S*<sub>1</sub> transcription is abolished and only low-level *S*<sub>2</sub> transcription occurs (~20-fold lower than the CRP-cyclic AMP-dependent *S*<sub>1</sub> transcription). However, CRP-cyclic AMP-independent *S*<sub>2</sub> transcription can be stimulated (~8–10-fold) by the addition of glycerol to the *in vitro* reaction<sup>15</sup>. Thus, using the appropriate *in vitro* transcription conditions, two distinct transcripts of the *gal* operon can be obtained which differ only in that one (CRP-cyclic AMP independent) has five additional nucleotide residues at its 5'-end compared with the other (CRP-cyclic AMP-dependent transcript) (Fig. 3).

RNA was prepared *in vitro* using DNA obtained from a  $\lambda$  transducing phage,  $\lambda_{pgal8}$ , which carries the entire *gal* operon within its genome (see accompanying paper, Fig. 1). These transcripts consist of the various  $\lambda$  mRNAs (described earlier), as well as the additional *gal*-derived polycistronic mRNA. Transcriptions were initially carried out either in the presence or absence of CRP-cyclic AMP and this RNA was then translated in the wheat-germ cell-free system (+SAM, as described in Fig. 1). RNA, prepared in the presence of CRP-cyclic AMP, directed synthesis of a new major protein product (~38,000 daltons, Fig. 1-9). Only minor amounts of this same protein were produced in a translation reaction carried out identically on RNA made in the absence of CRP-cyclic AMP (Fig. 1-8). Transcription of the *gal* operon, specifically induced by CRP-cyclic AMP, resulted in the corresponding translation of the 38,000-dalton protein. Cro protein was also made in these reactions (in response to the  $\lambda_{pR}$ -initiated mRNA); however, its synthesis was not affected by the presence or absence of CRP-cyclic AMP (compare Fig. 1-8 and 1-9). The CRP-cyclic AMP-dependent protein product is presumably *gal* epimerase (*E*), the 38,000-dalton protein encoded by the first cistron of the *gal* operon. Identification of the *gal E* product was confirmed by the translation of transcripts prepared from a mutant of  $\lambda_{pgal8}$ , which carries an ochre, chain-terminating mutation early within the *E* gene (S. Adhya, unpublished). These transcripts specifically failed to direct synthesis of the 38,000-dalton protein, whereas cro protein was produced normally (Fig. 1-12).

Analogous to the results obtained with both *cro* and cII, *gal E* translation in the wheat-germ system was also completely dependent on cap modification of the *S*<sub>1</sub>-initiated *gal* transcript. Addition of SAH to the translation reaction abolished synthesis of the *gal E* protein (as well as cro protein being synthesised in the same reaction, Fig. 1-10). In addition, *gal E* synthesis was markedly enhanced by cap modification of the RNA with the purified vaccinia enzymes before its translation. Although the *gal* mRNA encodes three gene products (*E*, *T* and *K*), again only the 5'-proximal *E* gene seemed to be translated efficiently. The AUG initiation codon for *gal* epimerase occurs only 27 residues from the 5'-cap-modified triphosphate end of the *S*<sub>1</sub>-initiated *gal* transcript<sup>15</sup>. It is difficult to compare the relative cap-dependent translation efficiencies of *gal E* and *cro* as the number of methionine residues in epimerase is not known. However, the *gal* promoter, even when stimulated 20-fold by CRP-cyclic AMP, is still less efficient *in vitro* than the  $\lambda_{pR}$  promoter. Thus, the apparently weaker translational response observed for *gal E* (compared to *cro*) results, at least in part, from the fact that there is less *gal* RNA produced in these transcription reactions than there is *cro* mRNA.

Several minor protein bands also seem to be synthesised in the wheat-germ extract in response to the CRP-cyclic AMP dependent *gal* transcript (Fig. 1-9). The appearance of these products was also sensitive both to the effects of SAH (Fig. 1-10) and to the introduction of the *gal E* ochre chain-terminating mutation (Fig. 1-12). These minor products probably result from premature termination of either *gal E* transcripts or translation products and were not further characterised.

**Fig. 2** Composite autoradiograph of a gel analysis showing the  $^{35}\text{S}$ -methionine-labelled products synthesised in wheat-germ extracts in response to RNA transcribed *in vitro* from the indicated phage DNAs (1–4) and a competition experiment comparing the relative translational efficiencies of *cro*, *gal E* and Hb mRNA (5)–(7), see below and text for details. Translation reactions 1–4 were carried out (as in Fig. 1) using the following components: (1) no added RNA (endogenous); (2) T7 early RNA (2.0  $\mu\text{g}$  total RNA containing  $\sim 1.0$  pmol of polycistronic T7 mRNA); (3) same as (1); (4)  $\lambda^+$  RNA, transcribed in the absence of *rho* factor (2.0  $\mu\text{g}$  total RNA containing  $\sim 1.0$  pmol of the  $p_R$ -initiated polycistronic *cro* mRNA). Translation reactions (5)–(7) were carried out (+5  $\mu\text{M}$  SAM) in reaction mixtures (50  $\mu\text{l}$ ) containing only 50% the wheat-germ extract (5  $\mu\text{l}$ ) as was used in all previous reactions (see Fig. 2 of the accompanying paper). This 'diluted' cell-free system was found to be saturated for translation of 3.0 pmol of Hb mRNA. Translations were carried out with the following components: (5) Hb mRNA only (3.0 pmol); (6) Hb mRNA (3.0 pmol) +  $\lambda\text{gal}18$  RNA (containing  $\sim 0.5$  pmol of *cro* mRNA and even less (but an undetermined amount) of *gal E* mRNA (see text)); (7)  $\lambda\text{gal}18$  RNA only (as in (6)). RNA was transcribed from T7 DNA as previously described<sup>29</sup>, with the following modifications: reaction volume (1.0 ml); T7 DNA (100  $\mu\text{g ml}^{-1}$ ); RNA polymerase (50  $\mu\text{g ml}^{-1}$ ). The T7 RNA directed translation products were identified by comparing their electrophoretic mobilities with those T7 products identified by Anderson *et al.*<sup>17</sup>. Apparent  $\lambda$  translation products ( $\rightarrow$ ), other than *cro* polypeptide, were not identified. Gel analyses of translation reactions (1)–(4) were autoradiographed for  $\sim 24$  h (twice the exposure time of all other gel analyses).

### *gal E* from another mRNA

Experiments similar to those described above were also carried out with RNA transcribed in the presence of glycerol using the  $\lambda\text{gal}18$  DNA template. Glycerol affects the level of RNA synthesis occurring from both the  $\lambda$  and *gal* promoters<sup>15</sup>. CRP-cyclic AMP-independent *gal* transcription (from start site  $S_2$ , Fig. 3) is increased 8–10-fold, whereas transcription of the  $\lambda p_R$  operon is enhanced only twofold<sup>15</sup>.

RNA was purified from a glycerol-stimulated transcription reaction and translated in the standard wheat-germ cell-free system. Again, two major protein products were synthesised: the 7,500-dalton *cro* protein and the 38,000-dalton *gal E* protein (Fig. 1–15). The translation system seems to have responded to the glycerol-enhanced levels of both *cro* and *gal* RNA (compare with Fig. 1–14). Using the same criteria as before, these transcripts were also shown to require cap modification for their translation in the wheat-germ extract (see, for example, Fig. 1–16).

*gal* mRNA stimulated with glycerol initiates at start site  $S_2$  and has a 5'-non-coding region 32 nucleotides long<sup>14</sup>. This places the cap structure 5 nucleotides farther from the presumptive *gal E* initiation site than occurs on the CRP-cyclic AMP-dependent,  $S_1$ -initiated mRNA. Although both

*gal* mRNAs are dependent on cap modification for their efficient translation in the wheat-germ system, these two messages exhibited different translation efficiencies. Approximately twice the amount of *gal* mRNA is made in the CRP-cyclic AMP-dependent transcription reaction compared with the glycerol-stimulated reaction<sup>15</sup>. However, the more abundant CRP-cyclic AMP-dependent  $S_1$  mRNA directed synthesis of less ( $\sim 50\%$ ) *gal E* protein than did the glycerol-induced  $S_2$  mRNA (compare Fig. 1–9, 15). Assuming that cap modification occurs to similar extents on the two different mRNAs, then the  $S_2$ -promoted mRNA is being translated 4–5-fold more efficiently than the  $S_1$ -promoted mRNA.

It was surprising that the *gal* mRNA was translated more efficiently when the cap moiety occurred 5 nucleotides farther from the translation start point. Presumably, the translational differences exhibited by the two *gal* mRNAs reflect the corresponding differences in their 5'-terminal structures (Fig. 3). The primary structural differences may affect the higher order structures (secondary and tertiary) exhibited by the non-coding leader regions of these two RNAs. Thus, the overall structure of the regions involved in recognition and initiation of *gal E* translation may be different in the two *gal* messages and thereby account for the differences in their translation efficiencies. As the translation system is derived from wheat-germ and requires cap modification of the *gal* mRNAs, the observed effects may be specific for translation in this particular system and therefore somewhat artefactual.

Alternatively, it is possible that the wheat-germ system is recognising and responding to a translational regulatory mechanism normally used to regulate *gal* enzyme levels in bacteria. The *gal* operon is known to be coordinately expressed when cells are metabolising galactose<sup>11</sup>. In the absence of galactose, however, *gal E* expression is constitutively required for bacterial cell-wall synthesis<sup>11</sup>. It has been postulated that the dual promoter system of *gal* regulates these different requirements for *gal* enzyme levels. Recent experiments (S. Adhya, personal communication) further indicate that, *in vivo* during CRP-cyclic AMP-independent *gal* expression, *gal E* activity is fourfold higher (whereas *gal K* activity is lower) than during CRP-cyclic AMP-dependent *gal* expression. If (as *in vitro*) the CRP-cyclic AMP-independent promoter (from  $S_2$ ) is less efficient at *gal* transcription than the CRP-cyclic AMP-dependent promoter (from  $S_1$ ), then perhaps the higher levels of *gal E* activity observed in the absence of CRP-cyclic AMP can be accounted for by more efficient translation of the  $S_2$ -initiated mRNA. If this is the case, then the wheat-germ components may not only be efficiently translating the cap-modified prokaryotic mRNA, but may also be responding to other translational regulatory signals encoded within these transcripts.

### Efficiency of capped and uncapped prokaryotic mRNAs

Identical amounts ( $\sim 0.5$  pmol) of *cro* mRNA were added to each of the translation reactions depicted in Fig. 3 of the accompanying paper. However, the amounts of *cro* protein synthesised in each of these reactions differed, due to the different relative extents to which the *cro* mRNA had been cap-modified in the various reactions. Approximately 60% of the *cro* mRNA (0.3 pmol) was shown to be cap-modified using the vaccinia enzyme. Translation of this RNA resulted in a  $>10$ -fold enhancement in *cro* protein synthesis, as compared with direct translation of the  $\lambda$  transcript (see accompanying paper<sup>1</sup>, Fig. 3–2, Fig. 3–6). If the translational activity exhibited by the *cro* mRNA is proportional to the number of functionally capped transcripts, then the amount of *cro* product obtained from direct translation of the  $\lambda$  RNA represents cap modification of  $<6\%$  of the input RNA (that is,  $<0.03$  pmol). Addition of SAM to the translation system was shown to stimulate *cro* translation about threefold. Thus, the wheat-germ extract seems to be capable (in the presence of SAM) of cap modifying about 15–20% of the input *cro* mRNA (that is,  $\sim 0.1$  pmol) and translating it with relatively high efficiency.

Our ability to detect readily the synthesis of the prokaryotic gene products in response to such small quantities of RNA is unprecedented. Other workers have reported accurate translation of several prokaryotic RNAs in various eukaryotic translation systems<sup>17-23</sup>. The quantities of RNA used in these studies and (where data are available) the relative yields of protein synthesis obtained suggest significantly lower translation efficiencies than those reported here for the cap-modified prokaryotic mRNAs. We were also able to demonstrate relatively low-level, cap-independent translation for several prokaryotic mRNAs. Transcripts were prepared using bacteriophage T7 DNA as template (see Fig. 2 legend). Anderson *et al.*<sup>17</sup> have demonstrated that T7 RNA is accurately translated in both a wheat-germ and a mammalian cell-free translation system. Furthermore, translation of this RNA was shown to be completely independent of cap modification. Although our results agree with theirs, we find that the T7 RNAs are translated relatively poorly when compared with the cap-modified  $\lambda$ , *gal*, or haemoglobin (Hb) mRNAs. Translation of 10-fold more T7 RNA (~1.0 pmol, Fig. 2-2) than capped *cro* mRNA (0.1 pmol; see accompanying paper, Fig. 3-4) resulted in the synthesis of significantly less T7 protein. It is difficult to compare precisely the synthesis of the T7 proteins with that of *cro*, as the number of methionine residues contained in the T7 protein is not known. Even if we assume that each of the T7 proteins contains only two methionine residues (as does *cro*), then their efficiencies of translation were 50-100 times lower than for *cro*.

Results similar to those observed with the T7 proteins were also obtained for several  $\lambda$  proteins. Addition of more polycistronic  $\lambda$  mRNA to the wheat-germ translation system and longer autoradiographic exposure times allowed detection of several other  $\lambda$  specific protein products (Fig. 2-4). Some of these polypeptides have MWs consistent with proteins known to be encoded by the polycistronic  $\lambda$  RNAs. These products have not been further characterised. Thus, the wheat-germ translation components can recognise and initiate translation of these other prokaryotic gene products, albeit at lower efficiency. Comparison (within the same reaction, Fig. 2-4) of the low-level synthesis of these proteins with the level of cap-dependent synthesis of *cro*, clearly demonstrates the importance of the cap structure for the efficient translation of the first gene in the polycistronic transcript.

### Efficiency of *cro* and Hb

The translation efficiency of the cap-modified prokaryotic mRNAs was also compared with that of purified Hb mRNA. Both *cro* protein and Hb protein have identical methionine contents and thus their abilities to be translated can be compared directly. In separate translation reactions, cap-modified *cro* RNA (~0.3 pmol) was shown repeatedly to direct higher levels of protein synthesis than did twice the amount of Hb RNA (~0.6 pmol; see accompanying paper, Fig. 3-6, Fig. 3-15). The capped prokaryotic transcript consistently translated about fivefold more efficiently than did Hb RNA in the wheat-germ extract. Experiments similar to these (unpublished) were also carried out using the standard reticulocyte lysate translation system. Again, *cro* RNA, cap-modified before translation with the vaccinia enzymes, was translated more efficiently than Hb RNA.

The remarkable ability of the capped, prokaryotic mRNA to be efficiently translated was even more pronounced when compared directly with Hb mRNA in the same translation reaction. Limiting conditions were found (legend to Fig. 2) in which the translation system was apparently saturated for the translation of Hb RNA. Using these conditions, RNA which had been prepared from a *λgal8* DNA template (in the presence of CRP-cyclic AMP) was added to the translation reaction (+SAM) simultaneously with saturating amounts of Hb mRNA (3.0 pmol). Although Hb RNA was present in about sixfold greater excess than total *cro* mRNA (~0.5 pmol), we observed a sharp reduction in the ability of the system to synthesise Hb

Fig. 3 The 5'-terminal nucleotide sequences of the RNA transcripts which encode the *Acro* protein (from promoter *p<sub>R</sub>*)<sup>30,31</sup>, the *λcII* protein(s) (from promoter *c17*)<sup>5</sup>, and the *E. coli gal* E protein (from the dual promoters *pgal*)<sup>13,16</sup>. The presumptive translation start sites for each polypeptide being translated in the wheat-germ cell-free extract is indicated AUG. The region of the RNA which precedes the AUG initiation codon for each protein, and which exhibits the most extensive complementarity to either the 3'-end of the prokaryotic 16S rRNA component (underlined) or the 3'-end of the eukaryotic 18S rRNA component (overscored) is also shown. The presumptive protein initiation sites for both *cII* proteins (*cIIa* and *cIIb*, see text) are indicated on the *c17* promoted transcript. The smaller polypeptide (*cIIb*) starts 22 amino acid residues (66 nucleotides) downstream from the start of the larger polypeptide (*cIIa*). The two transcription start sites (S<sub>1</sub> and S<sub>2</sub>) for *gal* mRNA synthesis are also shown<sup>14</sup>.

protein. Concomitantly, both *cro* and *gal* E proteins were readily produced (compare Fig. 2-5, Fig. 2-6). As the added prokaryotic mRNA had to be cap-modified during the translation reaction (in the presence of SAM), only 15-20% of the input *cro* message (that is, 0.1 pmol) accounted for the *cro* protein synthesised. Thus, the translation products shown in Fig. 2-6 actually represent those resulting from translation of an effective 30-fold difference in the amounts of capped *cro* and Hb mRNA (an even greater difference for the *gal* mRNA). The cap-modified prokaryotic message is clearly very efficient at competing for limiting eukaryotic translational components.

### Other implications

We have demonstrated the importance of the cap structure for obtaining efficient translation of certain prokaryotic mRNAs in a eukaryotic cell-free system. It is remarkable that cap modification of these transcripts is sufficient to result in their expression at levels which simulate (and actually surpass) those normally exhibited by many capped eukaryotic mRNAs. Our results indicate that, except for the cap modification, these prokaryotic mRNAs must contain all the essential structural information required for proper recognition and efficient synthesis by the eukaryotic translational components. Apparently strong evolutionary constraints have been placed on that portion of the mRNA structure that initiates translation, as well as on those regions of the ribosome which correspondingly interact with this RNA structure.

As the prokaryotic message does not require the cap structure for its normal expression in bacteria, our findings suggest that the steric requirements necessary for normal cap function are not too stringent. The positioning of the 5'-capped end of an RNA, however, is clearly subject to some structural limitations. Cap-dependent translation of the *λcII* gene was only obtained by positioning the cap structure nearer the *cII* coding region (through the *c17* mutation). The same *cII* coding information positioned ~330 residues from the cap structure was not translated effectively. RNA structural effects were also implicated in the apparent differential translation observed for the *gal* E protein from the two *gal* mRNAs. These observations suggest that prokaryotic and eukaryotic mRNAs may contain similar higher order structural requirements in those parts of the RNA molecule which are necessary for ribosome recognition and the initiation of protein synthesis.

Other signal sequences occurring on mRNA have been implicated in translational regulation<sup>24-28</sup>. The prokaryotic mRNA contains a region (of variable length) just preceding the AUG initiation codon (at a reasonably conserved distance), which is complementary to the 3'-terminus of the bacterial 16S rRNA components<sup>24-28</sup>. There is evidence that this region and its interaction with the 16S rRNA are important in the

translation of at least some prokaryotic mRNAs. It has also been suggested that the 5'-non-coding region of the eukaryotic mRNA may contain a similar type of recognition signal which correspondingly interacts with the 3'-end of the eukaryotic 18S rRNA component<sup>25</sup>. However, the heterogeneity in size and nucleotide sequence of the 5'-non-coding region of the eukaryotic mRNAs suggest that, except for the AUG initiation codon, it is difficult to find a conserved region which exhibits the necessary complementarity<sup>26,27</sup>.

The prokaryotic mRNAs used in our studies also exhibit little complementarity (except for the AUG initiation codon) to the 3'-end of the eukaryotic 18S rRNA. The  $\lambda$ cro and cII mRNAs, for example, can form only 3 A · U base pairs with the eukaryotic rRNA component. In contrast, these same mRNAs exhibit relatively extensive complementarities to the bacterial 16S rRNA component (Fig. 3). The ability of the prokaryotic mRNAs to be translated so efficiently by the wheat-germ system suggests that the necessity for the complementarity feature has been markedly diminished in the eukaryotic translation system. Although it is possible that an alternative recognition signal(s) has evolved in the eukaryotic mRNA, this signal should not be present in the prokaryotic message. As cap modification is the

only alteration required for efficient translation of the prokaryotic mRNA, perhaps the cap moiety now fulfills this recognition function.

The ability of the cap-modified prokaryotic message to compete efficiently with even saturating amounts of a eukaryotic mRNA (Fig. 2-6) suggests the possibility of obtaining high-level, functional expression of prokaryotic genes on their introduction into eukaryotic cells. Of course, appropriate transcriptional and post-transcriptional modification of the prokaryotic sequences would be required. Furthermore, it may be possible to increase the level of synthesis of essentially any gene product within a eukaryotic cell. Those prokaryotic sequences which contain highly efficient recognition signals for eukaryotic translational components (for example, 5'-non-coding region of the  $\lambda$ cro gene) could be fused (using available genetic engineering techniques) to eukaryotic sequences encoding protein structural information. Experiments of this nature are under way.

We thank Catherine Brady for technical assistance, Jean Regan for typing the manuscript, and Ray Steinberg for help with the illustrations.

### A kinematic model for SS433

THE bizarre object SS433, first noted because of its H $\alpha$  emission<sup>1</sup> and most recently because it is the optical counterpart of a variable radio and X-ray source<sup>2-4</sup>, exhibits an extraordinary optical spectrum<sup>5</sup>. Three sets of emission lines of hydrogen and helium appear: one is near zero radial velocity (less than 180 km s<sup>-1</sup>), and the other two show large and variable shifts to the blue and red. These shifts are almost unquestionably due to the Doppler effect, as multiple lines with constant  $z \equiv \Delta\lambda/\lambda$  have been identified in both the red and blue systems<sup>6-8</sup>. The observed range of shifts<sup>5,8</sup> corresponds to velocities from 0 to -30,000 km s<sup>-1</sup> in the blueshift system, and 11,000 to 48,000 km s<sup>-1</sup> in the redshift system, with the two sets of lines moving ~180° out of phase with each other. At present the red- and blueshift variations seem periodic, with a period of about 164 d, based on the observation of parts of three cycles<sup>7,8</sup>.

The emitting regions giving rise to the variable wavelength systems cannot be objects in mutual orbital revolution, for with a 164-d period and velocities of 0.15 *c*, keplerian orbits would have light-crossing times of the order of weeks, and the blue- and red-shifted emission lines could not continue to have simultaneous oppositions. The emission, therefore, must come from regions relatively close to a central object. A lower limit on the

distance to SS433, based on interstellar line strengths and velocities<sup>5</sup>, is about 3.5 kpc. The low velocity of the zero-redshift system suggests that the object is probably galactic, although certain *ad hoc* extragalactic hypotheses cannot be ruled out.

Milgrom<sup>9</sup>, independently of the present work, has also noted that the variations in redshift could be periodic and sinusoidal, and he considered several possible models to account for the variable velocity systems, including what we believe to be the correct one. In our judgement, Milgrom showed remarkable insight in interpreting the few data<sup>5</sup> then available to him. Now the much expanded observations<sup>8</sup> are sufficient to narrow the possibilities substantially.

We suggest here that the radiation with variable Doppler shift is emitted by hot matter ejected by the central object at high but nearly constant velocity in oppositely directed narrow streams, possibly along a magnetic axis. Rotation of the beam axis provides the observed radial velocity variations. This model is thus a modification of that proposed for SS433 by Fabian and Rees<sup>10</sup>, where the beam velocity is modulated to create these variations. In our interpretation for SS433, as the matter reaches a critical distance from the central object, it cools sufficiently to recombine and give rise to the observed emission. The stationary system of lines may originate from low velocity gas in the vicinity of the object or possibly from matter ejected at an earlier

time and later re-excited. The radiating matter could also be infalling along a collimated axis, although the source of such matter then requires special explanation. Conversely, the matter can be ejected (or infalling) isotropically from (or onto) the object, and be illuminated by two ionising radiation beams from the centre. The problem of accounting for the copious source of material in the latter case is far from trivial. We are concerned here not with a specific mechanism, but rather with a kinematic model that accounts for the current observations; it is very similar to model 3 suggested earlier by Milgrom<sup>9</sup>. Our model includes specific predictions regarding the behaviour of the variable velocity components during the as yet unobserved portions of the 164-d period. In particular, the behaviour in the summer of 1979 is predicted to show correlated variations with much lower amplitude than previously observed. This asymmetric behaviour, if observed, will provide some guide to the range of astrophysical mechanisms involved, and also yield direct observational evidence that the system period is actually 164 d, and not an integer multiple thereof.

We assume that the beam axis rotates with angular velocity  $\omega = 2\pi/164$  d. Although the cause of this rotation is unimportant to our simple kinematic description, note that the extremely high ratio of total system luminosity to the rotational energy of a compact star with a 164-d period implies that simple stellar rotation locked to the beams may not be the basic underlying system clock; precession is a possible alternative<sup>11</sup>. Let the line-of-sight lie along a unit vector  $\hat{n}$ , inclined at angle  $i$  to the beam rotation axis. As the beam axis rotates, the jets of flowing matter, orientated at angle  $\theta$  to the rotation axis, describe a conical motion about this axis, with period 164 d. Let the matter stream in opposite directions at speed  $v$  (in units where  $c = 1$ ), and let  $\mathbf{V}$  be the velocity vector of the stream in the same hemisphere as  $\hat{n}$ . The direction cosine,  $l$ , of the angle between  $\mathbf{V}$  and  $\hat{n}$  is

$$l = \frac{\mathbf{V}}{v} \cdot \hat{n} = \sin i \sin \theta \cos \omega t + \cos i \cos \theta$$

$$\equiv a \cos \omega t + b \quad (1)$$

The corresponding direction cosine,  $l'$ , of the angle between the line of sight and the opposite stream is

$$l' = -l = -a \cos \omega t - b \quad (2)$$

Note that

$$a + b = \cos |\theta - i|$$

$$\text{and} \quad b - a = \cos (\theta + i) \quad (3)$$

The Doppler shift is simply

$$1 + z = \gamma(1 + lv) \quad (4)$$

where  $l$  must be the direction cosine in the frame of the observer, and  $\gamma = (1 - v^2)^{-1/2}$ . The observed Doppler shifts of the streams with direction cosines  $l$  and  $l'$  are thus:

$$(1 + z) = \gamma(1 + va \cos \omega t + vb)$$

$$(1 + z') = \gamma(1 - va \cos \omega t - vb) \quad (5)$$

Thus  $va$  and  $vb$  are determined conveniently by observations of the ratio of  $(1 + z)$  to  $(1 + z')$  at any two phases and  $v$  follows from equations (5).

Figure 1 shows the measured Doppler shifts of SS433 obtained on 55 nights between June 1978 and April 1979, and folded with a 164-d period. These data were obtained from refs 5, 6 and 8, as well as re-interpretation of data<sup>4,12</sup> where wavelengths of the moving features were tabulated, but not previously interpreted as the Doppler effect. Note that a con-

**Fig. 1** Red- and blueshifts of SS433, measured on 55 nights during 1978–79, from sources cited in the text. The data have been folded with a 164-d period, and slightly more than one cycle is shown for clarity. The phase convention is arbitrary; as shown here, phase zero occurs on approximately 17 January 1979. The solid line is the prediction of the theoretical model described in the text, for beam velocity  $v = 0.270$ .

tiguous 35% portion of the entire cycle has never been observed. We take the point of largest amplitude of the radial velocity curves to correspond to the phase where  $\cos \omega t = 1$  (a choice of  $\cos \omega t = -1$  is simply a rotation of coordinates through  $180^\circ$ , and does not change the solution). Then the phase  $\cos \omega t = 0$  occurs at one-fourth cycle on either side of the maximum, and is a convenient second measurement point in our data. From Fig. 1 we find that the amplitudes of the radial velocity curves at the two relevant phases are: for  $\cos \omega t = 1$ ,  $(1 + z) = 1.175 \pm 0.005$  and  $(1 + z') = 0.903 \pm 0.005$ ; and for  $\cos \omega t = 0$ ,  $(1 + z) = 1.095 \pm 0.007$ ,  $(1 + z') = 0.982 \pm 0.005$ . We thus derive  $va = 0.0765$ ,  $vb = 0.0544$  and  $v = 0.270$ .

We cannot rule out a zero-point offset,  $\Delta$ , in the observed velocities due either to a cosmological (Hubble) redshift or gravitational redshift. Note, however, that the solution for  $va$  and  $vb$ , as described above, is independent of  $v$ . Because each depends on ratios  $(1 + z)/(1 + z')$ ,  $va$  and  $vb$  are also very insensitive to choices of moderate values of  $\Delta$ . Thus  $va$  and  $vb$  are well determined; a choice of  $\Delta$  determines  $v$ , and vice versa, but a range of values of  $\Delta$  and  $v$  are compatible with the data. However, a value of  $v > 0.270$  requires a positive value of  $\Delta$ , which if cosmological, requires that the system of stationary lines arises from gas with a velocity  $c\Delta$  in our direction, accidentally cancelling  $\Delta$ , and which if gravitational, poses severe difficulties in finding astrophysical mechanisms for the emission. To minimise such astrophysical problems and assumptions, we adopt  $\Delta = 0$  and  $v = 0.270$ . Then equations (5) generate the variation of  $(1 + z)$  and  $(1 + z')$  with phase, shown as smooth curves in Fig. 1.

We find the angles  $i$  and  $\theta$  from equations (3), but cannot tell which is which, that is  $(i, \theta) = (78^\circ, 17^\circ)$  or  $(17^\circ, 78^\circ)$ . The fact that the beams are found to lie at least  $61^\circ$  from the line of sight at all phases implies that any 164-d phase dependence of the moving system linewidths, caused by viewing the angular spread of the beam from different orientations, should be less than 13%, too small to be observable in our data sample.

Equations (5) also describe the situation<sup>9</sup> in which a rapidly revolving disk or ring of gas in a plane is illuminated by two pencil beams of ionising radiation from the central object, with a 164-d period of rotation. In this case, however, because the velocity variations are always confined to this plane,  $z = z'$  at  $\cos \omega t = 0$ , contrary to the observations of Fig. 1. Hence these ring or disk models must be ruled out.

In conclusion, Fig. 1 predicts that on or about 1 July 1979 the two moving emission line systems in SS433 will briefly merge.

into one, similar to a previously reported episode<sup>6</sup>, and that for the following 40 days the lines will separate again, but by an amount much less than previously observed.

We thank Drs H. Ford, J. Katz and J. Roberts for discussions, and R. Downes for aid in the data analysis. This work was supported in part by the US NSF.

## Is Cassiopeia A a black hole?

It is rather curious that no European astronomer observed the supernova which occurred in our Galaxy in about 1668 and left the remnant Cassiopeia A. However, if the absolute magnitude of the supernova is  $M_V = -19$  mag, the interstellar absorption is  $A_V = 4.3$  mag (ref. 1) and the distance is 2.8 kpc. Then its maximum visual magnitude should have been about  $-2.5$  mag. Even  $\sim 100$  d after the event, the supernova should have been as bright as any star in the Cassiopeia constellation. The fact that no such object was recorded suggests that the optical luminosity of the supernova may have been several orders of magnitude lower than the usual value. This note argues that the low luminosity of Cas A may be an indication that the product of the explosion is a black hole.

Recently Chevalier<sup>2</sup> hypothesised that Cas A was a 'dwarf' supernova born in the explosion of a fairly massive compact star whose photosphere extended not more than  $10^{12}$ – $10^{13}$  cm and which had lost its hydrogen-rich envelope during its evolution. The fact that pre-type I-supernovae are also compact objects which lost their hydrogen envelopes during their evolution<sup>3</sup> conflicts with that hypothesis. Formation of a rapidly rotating magnetised neutron star (that is, a pulsar) during the collapse causes powerful optical emission from supernovae of this type. It is the pulsar that is pumping energy into the expanding and adiabatically cooling shell of the exploded star. Recent calculations<sup>4</sup> have shown that such a 'slow' pumping of energy (as compared with the instantaneous explosion assumed in the previous models) can ensure the light curve observed for type I supernovae.

Since no sufficiently powerful optical emission was observed in the 'compact'-supernova event of 1668, we must conclude that, for some reason, it was not accompanied by the formation of a neutron star. It follows from X-ray radiation analysis of Cas A (ref. 5) that much gas ( $3$ – $6 M_\odot$ ) was ejected during the explosion.

All these observations indicate that the star which exploded and gave birth to Cas A was a very massive object. The analysis of X-ray observations, for example, implies that the mass of the hydrogen-rich shell which the star lost in the pre-explosion stage was at least  $10 M_\odot$ . Therefore, when it had been on the main sequence its mass was not less than  $20 M_\odot$ . This accounts for the unique character of the Cas A source: although it is already

about 300 yr old, there is no source brighter than Cas A among a dozen younger sources in the Galaxy. Why it is unique is obvious: very massive stars seldom form.

The example of Cas A shows that high mass stars first detach their hydrogen-rich shells and then—after about  $10^5$  yr—they explode without giving birth to a neutron star and without the associated intense optical outburst. (Note that if a neutron star had formed after the Cas A explosion a point source of soft X-ray radiation would be observed there; a neutron star could not cool down to less than  $3 \times 10^6$  K in  $300$  yr<sup>6</sup>.)

Thus after the explosion the star must either have completely dispersed, or most of its mass must have collapsed into a black hole. It is not yet possible to choose between these alternatives; but it is likely that in Cas A the gravitational collapse ended in the formation of a black hole. First, it follows from the relatively small mass of the hydrogen-depleted part of the exploded star (the part observed as fast moving filaments) as compared with the earlier-detached hydrogen rich shell. The chemical composition of the material in the fast-moving filaments is the most important argument favouring the conclusion that a black hole formed during the Cas A supernova event. The absence of elements of the Fe-group is highly characteristic of the spectrum observed for the fast-moving filaments. However, theoretical calculations of the star's expansion<sup>7</sup> lead us to expect that at least  $\sim 1 M_\odot$  of the exploded star should have transformed into Fe-group elements. In that case the spectrum of fast-moving filaments would inevitably have Fe II lines, in particular, the intense  $\lambda 4570$  line.

Thus the observations strongly support the conclusion that a black hole formed after the Cas A outburst.

## Millimetre and submillimetre measurements of the Crab Nebula

THE flux from the central region of the Crab Nebula in three broad spectral passbands with flux-weighted mean wavelengths of 300  $\mu$ m, 400  $\mu$ m and 1 mm have been measured. We report here that the inferred total flux densities for the entire nebula (Table 1) are consistent with an extrapolation of the power law spectrum found at longer wavelengths<sup>1</sup>.

The 300 and 400  $\mu$ m observations of the Crab Nebula were made with the University of Chicago f/13 photometer on the NASA Kuiper Airborne Observatory in September 1978. The detector was a Ga-Ge bolometer with heat trap field optics<sup>2</sup>. The system had a focal plane aperture of 1.9' and a chopper throw of 5.0'. The photometric pass bands were defined at short wavelengths by interference filters and at long wavelengths by diffraction and by the transmission characteristics of the light collector. We have measured the relative response of the photometer in the laboratory using both a grating spectrometer and a Fourier transform spectrometer. The two pass bands are shown in Fig. 1. W51 was used as the calibration source, assuming a spectrum of the form  $\nu B_\nu(T)$  where  $\pi B_\nu(T)$  is the

**Fig. 1** Relative responses of the passbands used for airborne observations. The solid and dashed curves have mean wavelengths of 300  $\mu\text{m}$  and 400  $\mu\text{m}$ , respectively.

Planck function. For a 1.9' aperture centred on the submillimetre peak of W51, we have assumed  $T = 40$  K and have normalised the function such that the flux density at 200  $\mu\text{m}$  is 24,000 Jy. These parameters give a good fit to measurements in the range  $80 \leq \lambda \leq 540$   $\mu\text{m}$  (refs 3–5) allowing for the effects of beam size. The signal-to-noise ratios for the Crab Nebula observations were 9 for the 300  $\mu\text{m}$  pass band and 3.6 for the 400  $\mu\text{m}$  pass band.

The 1-mm measurement was made with the Chicago  $f/7.5$  photometer at University of Hawaii 2.2 m telescope at Mauna Kea in September 1977. This detector also uses a Ga-Ge bolometer with heat trap field optics. The focal plane aperture and chopper throw were 3.2' and 8.0' respectively. The spectral response was defined by a helium temperature filter of fluorogold and black polyethylene, by the transmission of the atmosphere, and by diffraction. Jupiter was used as the calibration object with an assumed 750  $\mu\text{m}$  brightness temperature of 162 K (ref. 6). The Crab Nebula observations had a signal-to-noise ratio of  $> 6$ .

We derived flux densities from the observed signals by the methods described in ref. 7. The spectrum of the Crab Nebula was assumed to be proportional to  $\nu^{-0.26}$  in agreement with the radio spectrum; a change of  $\pm 0.25$  in the assumed spectral index produces a change of  $< 3\%$  in the derived flux densities. To allow for the effects of diffraction on the spectral response, we have assumed a gaussian source profile, convolved the assumed source with a diffraction pattern, and calculated the fraction of radiation within the focal plane aperture as a function of wavelength. The total flux densities in Table 1 were derived assuming a source size of  $2.3 \times 3.6'$  FWHM<sup>8</sup>. Errors of  $\pm 0.3'$  in both source dimensions result in errors of  $\leq 10\%$  in the obser-

ved flux density, but lead to errors of 15–20% in the extrapolation to total flux density. The estimated error in absolute calibration is  $\approx 20\%$ .

Werner *et al.*<sup>9</sup> have also measured the total flux density of the Crab Nebula at 1 mm. Their value,  $300 \pm 80$  Jy, is much larger than ours. The discrepancy is due primarily to the different methods used to obtain the total flux density. Werner *et al.* used a 1' beam to map the source and derived a total flux density from integration of their map. Their map shows a source with FWHM of  $4.5' \times 2.5'$ , although this size is somewhat uncertain due to the low signal-to-noise ratio in the outer regions of the map. The larger size leads to a higher total flux density. If we derive instead a total flux density from their observed central surface brightness and our assumed source size, we get a value of 210 Jy, in much better agreement with the value in Table 1. The question of the source size at wavelengths  $\leq 1$  mm deserves further study.

The total flux densities in Table 1 are consistent with a continuation of the radio spectrum into the submillimetre region with no change in slope (Fig. 2) although the errors would allow a change in slope of 0.25. However, the present data can be used to exclude more radical departures from the extrapolated radio spectrum. Kirshner<sup>10</sup>, for example, has suggested that the radio spectrum might steepen above 15 GHz. The resulting submillimetre flux densities would lie almost a factor of 3 below our measured values.

The present data show no increase in flux density at short-wavelengths which could be attributed to thermal radiation from

**Fig. 2** Spectrum of the Crab Nebula. Data sources: ○, this paper; 2.7 mm, ref. 8; 1 mm, ref. 9; 20  $\mu\text{m}$ , 11  $\mu\text{m}$  and 4.2  $\mu\text{m}$ , ref. 12; 4.75  $\mu\text{m}$ , 2.2  $\mu\text{m}$ , 1.65  $\mu\text{m}$  and 1.55  $\mu\text{m}$ , ref. 13; 3.5  $\mu\text{m}$  and 2.2  $\mu\text{m}$ , ref. 14; 100  $\mu\text{m}$ , ref. 15; radio and IR-optical fits, ref. 1.

**Table 1** Submillimetre flux density of the Crab Nebula

Mean wavelength ( $\mu\text{m}$ )	Observed flux density (Jy)	Total flux density (Jy)
300	$35 \pm 8^*$	$135 \pm 41^\dagger$
400	$41 \pm 14^*$	$158 \pm 63^\dagger$
1,000	$75 \pm 19^\ddagger$	$131 \pm 42^\dagger$

\* Into a 1.9' aperture. The error includes a 20% contribution from uncertainties in absolute calibration and in the assumed source spectrum.

† Assuming a gaussian source with FWHM of  $2.3' \times 3.6'$ . The error includes an additional 20% contribution due to the extrapolation to total flux density.

‡ Into a 3.2' aperture. The error includes a 20% contribution from uncertainties in absolute calibration, assumed source spectrum and atmospheric water vapour.

dust. From our measurement at 300  $\mu\text{m}$  we may place an upper limit on the dust emission within the range  $170 < \lambda < 900$   $\mu\text{m}$  equal to the observed flux,  $\nu F_\nu < 1.3 \times 10^{-12}$   $\text{W m}^{-2}$ . For dust spectra which have their peaks in this wavelength range, corresponding to  $T \leq 20$  K, our result improves the UCL limit of  $2 \times 10^{-10}$   $\text{W m}^{-2}$  between 40 and 350  $\mu\text{m}$ <sup>11</sup>.

At 100  $\mu\text{m}$  the best limit on the flux of the Crab Nebula is  $F_\nu < 275$  Jy<sup>15</sup>, which gives  $\nu F_\nu < 10^{-11}$   $\text{W m}^{-2}$ . We conclude that the luminosity of dust emission from the Crab Nebula is less than  $1300 L_\odot$  for dust with temperatures  $\leq 40$  K, but that there could be as much as  $5 \times 10^3 L_\odot$  emitted by dust with  $T \sim 120$  K.

## Acoustic absorption by $\text{MgCO}_3^0$ ion-pair relaxation

UNDERWATER sound propagation measurements in natural bodies of water frequently reveal attenuation anomalies that cannot be ascribed to known processes. When chemical relaxations are suspected, the acoustic resonator-decay method has proved an effective means of investigation in laboratory conditions. By stepwise synthesis of an artificial medium of similar composition and measuring changes in decay rates, the responsible chemical constituents can be identified. Then by combined stoichiometry and acoustic measurements with different concentrations, the relaxation kinetics of the reacting species can be determined. We have shown previously by resonator measurements that the acoustic absorption in Lake Tanganyika is the result of a chemical relaxation involving magnesium and carbonic acid<sup>1</sup>. The same relaxation is also believed to be responsible for one of the absorption components in seawater<sup>2</sup>. We show here that the relaxation kinetics follow a two-step association of the magnesium carbonate ion-pair.

If activity effects are neglected, the absorption arising from the slower second step of the two-step equilibrium  $\text{A} + \text{B} \rightleftharpoons \text{C} \rightleftharpoons \text{D}$  can be written

$$\alpha = \alpha_{\max} f^2 / (f^2 + f_r^2) \quad (1)$$

where  $f$  is the acoustic frequency and

$$\alpha_{\max} = \frac{(\Delta V)^2 k_2^- K_2 (C + D)}{2\beta_0 RT (1 + K_2)} \text{ neper s}^{-1} \quad (2)$$

Fig. 1 Measured decay rates against frequency for  $[\text{NaCl}] = 0.4 \text{ M}$  and  $[\text{CO}_2] = 2.5 \text{ mM}$ . ●,  $[\text{Mg}] = 5 \text{ mM}$ ,  $\text{pH} = 9.0$ ,  $pK'_{2C} = 9.56$ . ○,  $[\text{Mg}] = 50 \text{ mM}$ ,  $\text{pH} = 8.7$ ,  $pK'_{2C} = 9.17$ .

The respective concentrations are given by  $A$ ,  $B$ ,  $C$  and  $D$  and the equilibrium constants by  $K_1 = C/AB$  and  $K_2 = D/C$ . The relaxation frequency is given by

$$f_r = \frac{k_2^-}{2\pi} \left[ \frac{1 + K_1(1 + K_2)(A + B)}{1 + K_1(A + B)} \right] \text{ Hz} \quad (3)$$

where  $k_2^-$  is the reverse rate constant of step two and  $K_2 = k_2^+ / k_2^-$  where  $k_2^+$  is the forward rate constant. The effective change in molar volume is given by  $\Delta V = \Delta V_2 + \Delta V_1 / (1 + K_1(A + B))$  where  $\Delta V_1$  and  $\Delta V_2$  are the molar volume changes of the respective steps. Other constants are: compressibility,  $\beta_0 = 1/\rho_0 c_0^2$  where  $\rho_0$  is density and  $c_0$  is the speed of sound; gas constant,  $R$  and absolute temperature,  $T$ .

In the present case let  $A = [\text{Mg}^{2+}]$ ,  $B = [\text{CO}_3^{2-}]$  and  $C + D = [\text{MgCO}_3^0]$ . As  $\text{pH} > 7$  is the domain of interest, the carbonate-bicarbonate equilibrium is the only concern<sup>4</sup>. The equilibrium constant is given by  $K_{2C} = a_H[\text{CO}_3^{2-}] / [\text{HCO}_3^-]$  where  $a_H$  is the hydrogen ion activity.

To avoid inherent problems at low ionic strengths, all measurements were made in 0.4 M NaCl solutions. If other minor ion-pairings are neglected, the apparent equilibrium constant can be written<sup>5</sup>

$$K'_{2C} \approx K_{2C} (1 + K_1^* [\text{Mg}^{2+}] + K_2^* [\text{Na}^+]) \quad (4)$$

where  $K_1^* = [\text{MgCO}_3^0] / [\text{Mg}^{2+}][\text{CO}_3^{2-}]$  and where  $K_2^* = [\text{NaCO}_3^-] / [\text{Na}^+][\text{CO}_3^{2-}]$ . From this we have

$$[\text{MgCO}_3^0] \approx [\text{CO}_2] \frac{x}{1+x} \frac{y}{1+y_0+y} \quad (5)$$

where  $x = K'_{2C} / a_H$ ,  $y = K_1^* [\text{Mg}^{2+}]$  and  $[\text{CO}_2]$  is the total concentration. The apparent equilibrium constants were measured in a solution containing equal concentrations (1 mM) of  $\text{NaHCO}_3$  and  $\text{Na}_2\text{CO}_3$  which gives  $K'_{2C} \approx a_H$  or  $pK'_{2C} \approx \text{pH}$  ( $\text{pH}$  was measured by means of an  $\text{Ag}/\text{AgCl}$  electrode). The value  $y_0 = K_2^* [\text{Na}^+]$  was determined from the change in  $K'_{2C}$  when the NaCl was added. The value of  $K_1^*$  was then determined from the slope of  $K'_{2C}$  against  $[\text{Mg}^{2+}]$  measured when  $\text{MgCl}_2$  was added in steps. In the range of concentrations being considered, we have approximated  $[\text{Mg}^{2+}] \approx [\text{Mg}]$  where  $[\text{Mg}]$  is the total concentration<sup>6</sup>.

Our attention has been drawn to ref. 6 which shows that  $\text{MgCl}^+$  ion-pairing may also be important. To account for the reduced free ion concentration we can write  $[\text{Mg}^{2+}] \approx \text{constant} \times [\text{Mg}]$ . However, as  $K_1^*$  was measured in identical conditions, its value must be correspondingly increased which leaves the results of equation (5) unchanged.

All measurements were made at 22 °C. The resonator apparatus and procedures are described in ref. 2.

Figure 1 shows typical measurements of decay rates against frequency. The data are fitted by equation (1) which gives  $\alpha_{\max}$  and  $f_r$  for each set of experimental conditions. The  $\alpha_{\max}$  values were normalised by the formula  $\alpha_{\infty} = \alpha_{\max}(1+x)/x$ . Thus  $\alpha_{\infty}$  is the value one would have for  $pH \gg pK'_{2C}$ , that is, if all  $CO_2$  were in the form of the three carbonate species. The values were converted from  $dB\ s^{-1}$  to  $Np\ s^{-1}$  by dividing by 8.7.

The  $\alpha_{\infty}$  and  $f_r$  data are shown in Fig. 2. The  $f_r$  data were fitted by equation (3) using the measured value  $K_1^* = K_1(1+K_2) = 160/M$  with  $K_2 = 2$  and  $k_2^- = 6 \times 10^4\ s^{-1}$ . The  $\alpha_{\infty}$  data were fitted

**Fig. 2** Absorption  $\alpha_{\infty}$  and relaxation frequency  $f_r$  plotted against magnesium concentration for 0.4 M NaCl solution. Similar curves would be obtained for Lake Tanganyika conditions except that the [Mg] scale would be roughly an order-of-magnitude smaller because of the much greater values of  $K_1^*$  at low ionic strengths.

using the value  $\Delta V = \Delta V_2 = 12\ ml/M$  in equation (2) and the measured value  $y_0 = 3.5$  with  $x \gg 1$  in equation (5).

The agreement between theory and experiment shows that the absorption mechanism in question can be modeled as the two-step  $MgCO_3$  equilibrium in which the slower second step controls the relaxation process. The calculated rate constants should be valid for both Lake Tanganyika and seawater at 22 °C. It appears, therefore, that the earlier estimate of the Lake Tanganyika relaxation frequency (40 kHz) is too high. Present measurements indicate that it should be no greater than 30 kHz.

Calcium ion-pairing may not entirely account for the reduced absorption when  $CaCl_2$  is added<sup>1,2</sup>; hence, a decrease in  $\Delta V_2$  may also be involved. In seawater, calcium evidently provides the coupling between the magnesium carbonate and the boric acid/borate equilibria that is responsible for an order of magnitude increase in the relaxational absorption of the latter<sup>7</sup>.

## Anomalous characteristics of the microcrystalline state of SiC fibres

FIBRES of SiC are prepared<sup>1-4</sup> from the polycarbosilane which, in various forms, is made into a precursor by melt-spinning: the precursor is then heated to produce the SiC fibre. Ceramics are produced in this way by heating the organosilicon polymer. The organic precursor is prepared in a subtle form (for example, as fibres) which is extremely difficult to produce from an inorganic precursor. On heating the organic precursor a ceramic skeleton remains. This inorganic residue derived from an organosilicon polymer possesses characteristics not previously known and these are reported here.

Table 1 shows a chemical analysis of the SiC fibre obtained after heat-treatment (1,300 °C) of the precursor fibre. Its atomic ratio is Si:C:O:H = 1:1.46:0.36:0.03. Table 1 shows that the SiC fibre contains appreciable amounts of carbon and of oxygen which had been introduced by the heating of the precursor fibre. Assuming then that the oxygen is present in the fibre as  $SiO_2$ , the molar ratio of compounds in the SiC fibre is  $SiC:C:SiO_2 = 1:0.78:0.22$ .

The apparent density of the  $\beta$ -SiC fibre obtained by heating a precursor fibre at 1,300 °C is  $2.6\ g\ cm^{-3}$ , which is lower than the true density  $3.2\ g\ cm^{-3}$  of  $\beta$ -SiC.

**Fig. 1** High resolution electron micrograph of a precursor fibre heat-treated at 1,300 °C.

**Table 1** Composition (wt%) of fibres

	Si	C	O	H
Precursor fibre	46.8	38.1	0.82	7.40
Fibre after curing	44.4	31.0	15.5	5.30
SiC fibre	50.5	31.6	10.3	0.055
SiC fibre after heat treatment at 1,250 °C	51.3	23.9	18.5	0.015

The SiC fibre possesses a high tensile strength ( $350 \text{ kg mm}^{-2}$ ), a diameter of  $10 \mu\text{m}$  and a high Young's modulus ( $20 \text{ tonnes mm}^{-2}$ ). The fibre sustains a load of  $200 \text{ kg mm}^{-2}$  at  $1,250^\circ\text{C}$  for 3 d in air. Table 1 shows a chemical analysis of the SiC fibre after heat-treatment. Its compound molar ratio is  $\text{SiC}:\text{C}:\text{SiO}_2 = 1:0.59:0.46$ ; a lot of carbon still remains.

The tensile strength and the Young's modulus of the SiC fibre are independent of temperature (between room temperature and  $1,400^\circ\text{C}$ ) *in vacuo*<sup>5</sup>, and the strength at the high temperature in air<sup>6</sup> is as good as other silicon carbide fibres<sup>7,8</sup>.

$\text{SiO}_2$  is considered mainly to exist at the surfaces of the SiC fibre. We investigated how the SiC and the excess carbon come to exist in the fibre.

It has been previously reported that in the SiC fibre, the SiC matrix is distributed uniformly as fine grains from the result of X-ray diffraction<sup>1-4</sup>. Figure 1 shows a high-resolution electron

**Fig. 2** Variation of the tensile strength of precursor fibres with heat-treatment temperatures.

micrograph of the powdered SiC fibre. The fibre was prepared by heating a precursor fibre at  $1,300^\circ\text{C}$  in a vacuum. The lattice image corresponding to a  $2.5 \text{ \AA}$  interlayer spacing of  $\beta\text{-SiC}$  (111) planes and a  $3.4 \text{ \AA}$  interlayer spacing of graphite (002) planes are observed. The SiC is ultrafinely grained. Figure 1 also indicates a uniform distribution of fine grains of carbon surrounded by  $\beta\text{-SiC}$ . It is difficult for the fibre in this condition to be oxidised. A high-resolution electron micrograph of SiC fibre after the  $1,250^\circ\text{C}$  heat-treatment was also taken. The distribution of carbon was almost the same as before the heat treatment.

The excess carbon and the oxygen introduced in the curing process may affect the microcrystalline state of  $\beta\text{-SiC}$ . The relationship between the mechanical strength of the fibre and the heating temperatures for the precursor fibre *in vacuo* is shown in Fig. 2. Heating at  $1,500^\circ\text{C}$  causes the mechanical strength to drop, as shown in Fig. 2. Figure 3 shows the X-ray (Ni-filtered  $\text{Cu K}\alpha$ ) diffraction patterns of the precursor fibre heated at  $1,000$ ,  $1,100$ ,  $1,200$ ,  $1,300$  and  $1,500^\circ\text{C}$ . The X-ray diffraction patterns on heating at  $1,500^\circ\text{C}$  indicate a larger fraction of crystallised  $\beta\text{-SiC}$  in comparison with the patterns of fibres heated at  $1,100$ – $1,300^\circ\text{C}$ . The mechanical strength drops with crystallisation of the  $\beta\text{-SiC}$ . The stable and uniformly distributed carbon in the SiC fibre may be precipitated with

**Fig. 3** X-ray diffraction patterns of precursor fibres heat-treated at various temperatures. Full-scale intensity of patterns at  $1,100$  (b);  $1,200$  (c); and  $1,500^\circ\text{C}$  (e) is twice that of patterns at  $1,000$  (a) and  $1,300^\circ\text{C}$  (d).

crystallisation of the  $\beta\text{-SiC}$  phase, hence lowering the mechanical strength: in other words, the SiC fibre in the microcrystalline state has high mechanical strength.

Chemical analysis of the SiC fibre and its high-resolution electron micrograph show an unexpectedly large quantity of excess carbon existing in the fibre. In spite of this, this fibre has a high strength and a high heat-resistance at high temperatures.

## Spontaneous formation of lecithin bilayers at the air–water surface

THE energetics of formation of various surface film states of dimyristoyl lecithin (DML) has been recently obtained from equilibrium spreading pressure  $\pi_e$  measurements<sup>1</sup>. One result from that study, but not reported then, was the formation of a new equilibrium lecithin surface phase. Its existence was deduced solely from formal thermodynamic arguments based on the Gibbs phase rule, and therefore reporting of the new surface phase was deferred until more direct experimental evidence was available for describing its properties. We have now characterised this new surface phase by measuring the surface concentration of DML films and have found the concentration to be double that of a close-packed monomolecular film. Before presenting these results and their implications, we summarise the arguments which led to the prediction of the new lecithin surface phase.

In principle,  $\pi_e$  measurements as a function of temperature indicate the existence of all phase transitions; they also provide a thermodynamic basis for calculating transition energies<sup>2–4</sup>. The equilibrium surface phase relations for DML obtained by this approach in the region of  $T_c$ , the gel–liquid crystal transition temperature, is given in Fig. 1a. Line ABCD represents the coexistence line for the equilibrium of surface film with bulk DML, either gel or liquid crystal. Point B is at 23.5 °C,  $T_c$  for DML. At temperatures below  $T_c$ , the bulk gel state is in equilibrium with a gaseous surface film; at temperatures above  $T_c$  liquid crystal is in equilibrium with a gaseous film which changes with increasing temperatures into a liquid expanded film along line CD. Line CE represents the equilibrium of liquid expanded film with surface gas in the absence of bulk lipid; these values of  $\pi$  are the equivalent of the surface vapour pressure<sup>1</sup>. Line CE' represents the supercooled liquid expanded film surface vapour pressure; it is formed when solvents are used to form the film at temperatures below 25 °C (ref. 1).

The phase line CD which describes the equilibrium between liquid crystal and liquid expanded film indicates that  $\pi_e$  increases rapidly with temperature. But  $\pi_e$  must reach a finite limit at some elevated temperature. Indeed, measurements of  $\pi_e$  for DML at temperatures exceeding 25 °C, shown in Fig. 1, indicate that  $\pi_e$  reaches a maximum of 49.5 dyn cm<sup>–1</sup> at about 29 °C. With further increase in temperature  $\pi_e$  decreases slightly. Similar results were obtained by Phillips and Hauser<sup>5</sup>.

The Gibbs phase rule at constant atmospheric pressure for this system<sup>6</sup> may be written

$$F = C - P_s - P_b + 2$$

where  $C$  is the number of components (water, lecithin, and air),  $P_s$  and  $P_b$  are the number of surface phases at the air–water surface, and bulk phases, respectively, and  $F$  is the number of intensive variables (temperature and chemical potential) which may be varied independently. For this system, with bulk lipid and at least one surface phase always present,  $F$  is either 1 or 0. Thus, when  $\pi_e$  varies with temperature,  $F = 1$  and the chemical activity of lipid in each equilibrium phase also varies with temperature. Examples are given in Fig. 1a, along line AB where  $P_b = 3$  (gel, water, air),  $P_s = 1$  (surface gas), and along line BC where the bulk lipid gel state becomes liquid crystal at the elevated temperatures. At the gel–liquid crystal transition temperature, point B (Fig. 1),  $F = 0$ , as  $P_b = 4$  (gel, liquid crystal, water, air), and  $P_s = 1$ .

At temperatures above and below 29 °C (the temperature where  $\pi_e$  is a maximum)  $\pi_e$  is also temperature dependent,  $F = 1$ , and therefore homogeneous surface films exist both below and above 29 °C. However, at 29 °C  $F = 0$ , and the phase rule therefore indicates that a phase transition occurs just as at

point B (Fig. 1); this new phase transition may be either in the surface or bulk. Because the temperature where this occurs exceeds  $T_c$ , the only lipid bulk phase present is the liquid crystal. As there is no evidence for a DML bulk phase transition at 29 °C, we deduce that at the temperature where  $\pi_e$  is a maximum, DML forms a new surface phase. To establish that the new phase which appears at 29 °C is in the surface, DML surface concentrations were measured by two independent methods.

**Fig. 1** a, Surface pressure  $\pi$  as a function of temperature in the region of the gel–liquid crystal transition temperature,  $T_c$  for DML. For explanation of phase diagram see text, and ref. 1. b, Complete equilibrium spreading pressure  $\pi_e$ –temperature diagram for DML. Note change in scale for  $\pi$ . Wilhelmy plate method used for this data, sensitivity of the order of 0.1 dyn cm<sup>–1</sup>. Data for the figure inset were obtained by the millidyne balance<sup>1</sup>. Therefore the details seen in the inset are not observed in the expanded range figure.

The first method entails isolating and collecting the surface film which accumulates in the air–water surface when DML crystals are placed on the water surface. A temperature controlled ( $\pm 1^\circ$ ) film balance trough was divided into two compartments by a strip of Teflon. The strip has a slit on its upper edge to allow a small connection at the surface between the two water compartments. Bulk lipid was placed on the water surface of one compartment and held in place by a platinum wire loop; the second compartment was monitored for changes in  $\pi$  by the Wilhelmy plate technique. The bulk lipid generally remained effectively trapped behind the Teflon strip separating the two compartments. Films which accumulate at the surface of the second compartment were swept by a Teflon barrier over the edge of the trough and across a collection spout into beakers. The water which is entrained with the lipid amounts to about

0.01 ml cm<sup>-2</sup> of surface film<sup>7</sup>. This water was evaporated and the dried phospholipid was analysed for phosphorus<sup>8</sup>. Generally 350–400 cm<sup>2</sup> of surface was sufficient to provide enough lipid for the analysis. The films were collected 2 and 4 h after the surface pressure had ceased to change; the time interval had no significant influence on the amount of material collected.

For the second method the surface concentration was obtained by measuring the surface radioactivity of <sup>3</sup>H-DML adsorbed from equilibrium dispersions of DML. The dispersions of DML gave identical values of  $\pi_e$  as those obtained by spreading from the crystal. A thermostatted ( $\pm 0.1^\circ$ ) glass cell was used for both the  $\pi_e$  and radiotracer measurements of the dispersions. Specific activity of <sup>3</sup>H-DML was approximately 35 Ci mol<sup>-1</sup>, (a purified sample provided by Dr R. E. Pagano). Surface radioactivity was monitored by an end-window gas-flow detector; the window was composed of Parylene<sup>9</sup> with a vacuum deposit of gold (approximate thickness: 70  $\mu$ g cm<sup>-1</sup> Parylene, 30  $\mu$ g cm<sup>-1</sup> gold). The detector was constructed by the Aloka Company, Mitaka, Japan, and was used with a standard scalar (Nuclear-Chicago, model 168). The counting efficiency of the detector was about 2% at a height of 1 mm above the water surface. Surface radioactivities were not affected by bulk particles of DML in the dispersion because the lipid density is greater than for water<sup>10</sup>, thus these particles settled out of the range of tritium ( $\sim 1 \mu$ m in water) within 30 min. More complete details of the method will be presented elsewhere. Dispersion concentrations of 0.1–1.0 mg ml<sup>-1</sup> were used and the reported surface radioactivities were found to be independent of the dispersion concentrations.

The surface concentrations of DML as a function of temperature obtained by both methods is shown in Fig. 2. The values of  $\Gamma$  obtained by the two methods are in general agreement, with the larger error of the sweeping experiments reflecting the multiple operations required for the analysis. Below 25 °C where the equilibrium surface pressure is very low (surface gas region, Fig. 1) the surface concentration is close to zero. With increasing

temperature, the surface concentration increases to a maximum value of  $6.4 \times 10^{-10}$  mol cm<sup>-2</sup> at about 29 °C. At still higher temperatures  $\Gamma$  decreases monotonically to  $3.2 \times 10^{-10}$  mol cm<sup>-2</sup> at about 35 °C.

Film balance studies indicate that close-packed monolayers occupy 50–55 Å<sup>2</sup> per molecule or  $3.3\text{--}3.0 \times 10^{-10}$  mol cm<sup>-2</sup> (ref. 11). Thus the adsorbed film formed at 35 °C (Fig. 2) appears to be a close-packed monolayer; at 29 °C the surface concentration is exactly double that of the close-packed monolayer, or the equivalent of a bilayer. The formation of the surface bilayer is not fortuitously dependent on the experimental conditions because its formation is independent of the dispersion concentration, and the same results were obtained by two independent methods. Moreover, the temperature of surface bilayer formation coincides with the temperature in which  $\pi_e$  is a maximum (Fig. 1b), and for which the phase rule predicts that a new lecithin phase appears. The new surface phase predicted by the phase rule is the surface bilayer.

While we cannot ascribe molecular configurations to the surface films which are reported in these studies, hypotheses consistent with the phase rule are suggested for describing the surface phase transitions. Figures 1 and 2 indicate that DML surface films between 25 and 29 °C pass continuously from the gaseous to the bimolecular state. As the phase rule predicts that a single homogeneous surface phase is present, we assume that at each temperature in this interval states of aggregation intermediate between gaseous and bilayer are formed. Between 29 and 35 °C the data suggests that the surface bilayer reverts to a condensed monolayer structure. In this interval the phase rule indicates that the surface film is homogeneous, but that surface bilayer must also be present. We therefore deduce that bilayer is transformed continuously to condensed monolayer, but assume that monolayer which forms is completely miscible with the bilayer, that is both monolayer and bilayer coexist in a homogeneous surface phase. At temperatures exceeding 35 °C condensed monolayer is the only surface state present. Phenomenologically, DML forms in sequence with increasing temperatures: gaseous film, surface bilayer and finally condensed monolayer.

Several additional aspects of this system are noteworthy. The surface bilayer will form only in the presence of bulk phase liquid crystal, and at a unique temperature which is presumably a characteristic of each lecithin. In equilibrium conditions the surface bilayer will not exist independently of multilamellar liquid crystal. Questions on the generality of these phenomena and the thermodynamics of formation of surface bilayers will be examined in detail elsewhere. Finally, it has always been a basic tenet of lipid film studies on water that the films may be assumed to be monomolecular. We have shown that for at least one equilibrium system, surface films can exceed monolayer concentrations.

## Thermoluminescence dating of a deep-sea sediment core

IN the last decade thermoluminescence dating has been developed for use on archaeological material, principally pottery, that was heated in antiquity<sup>1</sup>. Thermoluminescence (TL) is the light emitted by a material when heated and which results from a previous dose of radiation. In the simplest cases the light intensity is proportional to the radiation dose and can be used for determining an unknown dose; when combined with other measurements which yield the dose rate the TL can thus be used to calculate an age. In the case of pottery the event being dated is the last heating of the material to a high temperature, typically 500 °C. The use of TL to date the deposition of ocean sediments which we propose here is similar in the main principle except for the lack of the heating event. We describe here the experimental evidence which indicates that some event which has the same result does occur. We then show that exposure to sunlight could be this event, and finally show that TL dates obtained for an ocean sediment core are in agreement with dates determined independently.

The results presented here are for 4–11- $\mu$ m grains of samples of the deep-sea core RC8–39 from the Crozet Plateau of the Antarctic Ocean (long 42°21'E, lat 42°53'S, water depth 4,330 m). The sample preparation and measurement techniques are based on those of Zimmerman<sup>2</sup> and will be described in detail elsewhere.

Figure 1a shows a typical glow curve obtained for the sample at 580 cm below the top of the core. All the other samples gave similarly shaped glow curves but with an overall increase of TL intensity with depth down the core. A convenient measure of the TL intensity is the  $\gamma$ -radiation dose,  $D$ , that produces the same TL; we determined this using the additive dose method<sup>1</sup> in which the TL of the samples is compared with the TL of identical samples which have also received a laboratory radiation dose. Figure 2a shows the value of  $D$  obtained for each sample at the 300 °C glow-curve temperature, and that  $D$  increases with depth down the core.

A similar increase of TL with depth was previously reported in two North Pacific cores by Huntley and Johnson<sup>4</sup>. They thought that the TL was coming from the separated siliceous tests; however, we have since discovered that it was coming primarily

**Fig. 1** Thermoluminescence glow curves from RC8–39 580 cm: a natural; b natural sample after a 40-min sunlamp exposure, c–e as b but after additional  $\gamma$  doses of 7.4, 14.8 and 22.2 krad respectively.

**Fig. 2** ○, The TL intensity against depth for RC8–39 evaluated at a glow-curve temperature of 300 °C.  $D$  is the  $\gamma$  dose which produces the same TL as observed in the natural samples and was obtained by the additive dose procedure. ×, Values of  $D_0$  for the same samples.

from the inorganic sediment still attached to the siliceous tests. In all three cores the TL of samples near the top of the core is significantly less than the TL of samples with an age of  $\sim 10^5$  yr. We have found a similar low TL intensity in four other core top samples we have studied. We deduce, therefore, that the TL of freshly deposited sediment is small, and not in saturation as one might expect for material derived from terrestrial sources.

Further evidence for a low TL level in freshly deposited sediment is found in the TL studies of Quaternary sediments in the USSR<sup>5–9</sup> and China<sup>10</sup>. Here an increase of TL with depth was also observed. In the original Soviet work Morozov<sup>5</sup> and Shelkopyas<sup>6</sup> suggested that the effects of sunlight and grinding during weathering were responsible for the low level of TL in freshly deposited sediments. Consequently we have examined the effects of sunlight on the TL of our samples and found a remarkable sensitivity: 20 min of exposure is enough to halve the natural TL.

To test the proposal that exposure to sunlight is a viable mechanism for setting the natural thermoluminescence to near zero we gave a set of identical samples a large  $\gamma$  dose ( $\sim 400$  krad), to bring them near saturation, and then measured the TL as a function of light exposure. This experiment was performed with a Sylvania sunlamp which is about four times as efficient as sunlight so that reproducible exposures could be obtained. The results, in Fig. 3, show that an exposure equivalent to  $\sim 10$  d of direct sunlight is capable of reducing the TL to the level found in a sample at the top of the core. Hence we suggest that previously acquired geological TL could be erased by exposure to sunlight before deposition on the ocean floor. However, we have not carried out any detailed mineral separation and chemical and mechanical alteration during weathering and sedimentation may play a significant role as well. Whatever the cause of the low TL in freshly deposited sediment the following arguments may still be applied.

As Fig. 3 shows, even after long light exposures there is a finite TL signal. (This may be due to the presence of a TL signal that cannot be bleached easily or may be due to a non-radiation-induced signal.) We therefore describe the natural TL of a sediment sample by

$$I_{\text{nat}} = I_o + I_d \quad (1)$$

where  $I_o$  is the TL at the time of deposition and  $I_d$  is the TL due to the radiation dose since deposition. Ideally a core top sample should yield a TL signal  $I_o$ . In practice, however, its TL may also be expected to have a small  $I_d$  component due to the real age of the material because of loss of the most recent sediment during coring and because of sediment mixing due to bioturbation<sup>11</sup>.

Rewriting equation (1) in terms of the  $\gamma$  doses that produce the same TL intensities we have

$$D = D_o + ED \quad (2)$$

where  $ED$ , the equivalent dose, is that laboratory  $\gamma$  dose that produces the same TL intensity as did the radiation dose experienced by the sample since deposition.

To determine  $ED$  we have developed the procedure shown in Fig. 1. All measurements are made on separate identical samples. Curve  $a$  is the TL of a natural sample. Curve  $b$  is the TL of a similar sample exposed to the sunlamp for 40 min. Curves  $c-e$  are the TL values of samples exposed to the sunlamp and then given various  $\gamma$  doses. Figure 1 shows that a  $\gamma$  dose of about 13 krad would give a TL similar to that of the natural sample above 250 °C. This dose is called  $G$ . Figure 3 shows that the 40-min sunlamp exposure was not sufficient to remove all of the  $I_d$  component of the natural TL. Let us call the fraction that remained  $f$ . Then we have

$$ED = \frac{G}{1-f} \quad (3)$$

We have determined  $f$  in separate experiments in which samples were first given long sunlamp exposures,  $\gamma$  irradiated, and then given 40-min sunlamp exposures. The values of  $f$ , typically 0.2, did not depend measurably on the  $\gamma$  dose or core sample.

We tested the above procedure for obtaining  $ED$  by using it to determine the dose for samples which had been given a known laboratory dose after a substantial sunlamp exposure. As an additional test we have taken several sets of the 119 cm samples, given them known  $\gamma$  doses,  $\Gamma$ , in addition to the natural dose, and then used the above procedure to determine  $G$  for each set. The plot of  $G$  against  $\Gamma$  was linear and when extrapolated to  $G=0$  yielded a value  $\Gamma = -ED$  independent of temperature above 250 °C and in accord with the one obtained by the

previous method. The above tests gave agreement within  $\pm 5\%$ .

The equivalent doses we have determined using equation (3) for six samples of RC8-39 are listed in Table 1. The increase with depth closely parallels that shown in Fig. 2. Values of  $D_o$  were obtained, by subtraction ( $D_o = D - ED$ ), and those at 300 °C are shown in Fig. 2; they show no systematic variation with depth and therefore are consistent with the model.

From the equivalent doses listed in Table 1 we have calculated TL ages using radiation dose rates determined by the standard techniques worked out for TL dating of archaeological material<sup>1</sup>. The age equation we have used is

$$ED = (R_K + R_U + R_{Th})T + R_1\tau\{\exp(T/\tau) - 1\} \quad (4)$$

where  $T$  is the age, the  $R$  values are the effective radiation dose rates due to the decay of  $^{40}\text{K}$ ,  $^{238}\text{U}$ ,  $^{232}\text{Th}$  and  $^{230}\text{Th}$  respectively and include  $\alpha$ ,  $\beta$  and  $\gamma$  contributions. The last term, which is dominant arises from the presence of excess  $^{230}\text{Th}$  which is continuously precipitated from the ocean; the  $^{230}\text{Th}$  mean life  $\tau$  is 108 kyr and thus it is necessary to include the variation of dose rate with time. Each term in the equation includes a water

Fig. 3 The fraction of the TL evaluated at a glow-curve temperature of 300 °C remaining after a sunlamp exposure against exposure time. The experiment was performed on a set of samples which had been given a laboratory dose of 400 krad to simulate their condition before weathering.

attenuation factor calculated using an estimated water content of  $57 \pm 5\%$ , and each  $\alpha$  dose-rate term includes a measured TL efficiency factor<sup>12</sup>. The  $^{238}\text{U}$ ,  $^{232}\text{Th}$  and  $^{230}\text{Th}$  contents were determined using  $\alpha$ -scintillation counting and the dose rate conversion factors calculated according to the method described by Bell<sup>13</sup>.

The ages thus calculated are shown in Table 1 where they are compared with those we have deduced from the *Cycladophora davisiana* and oxygen-isotope variation curves of Hays *et al.*<sup>3</sup>. We consider the correlation between the two sets of dates to be sufficiently encouraging to suggest that the method is basically sound. Complete details of the measurements will be published elsewhere.

We thank M. J. Aitken, W. Blake Jr, B. D. Bornhold, J. D. Hays, H. P. Johnson, D. E. Nelson, N. J. Shackleton and the late D. W. Zimmerman for advice. The work was supported by grants from the Department of Energy, Mines and Resources, and the NRC of Canada. The sediment core samples were kindly provided by the Lamont-Doherty Geological Observatory; ONR grant N00014-75-C-0210 and NSF contract OCE76-18049 are acknowledged in this respect. A.G.W. received a

Table 1 Doses, radioactivity analyses, TL ages and *C. davisiana* ages for RC8-39

Depth (cm)	Equivalent dose (krad)	K content (%)	Measured $\alpha$ -count rate ( $\text{ks cm}^{-2}$ ) <sup>-1</sup>	TL age (kyr)	Age from <i>C. davisiana</i> (kyr)
9	3.0	0.33	$1.83 \pm 0.03$	9	6-10
118	7.2	0.82	$1.25 \pm 0.02$	30	22-25
230	10.6	0.55	$0.98 \pm 0.02$	51	40-46
342	19.1	0.71	$1.02 \pm 0.03$	$\geq 76$	58-66
580	15.7	0.42	$0.77 \pm 0.01$	85	85-90
902	25.6	0.53	$0.56 \pm 0.01$	140	125-135

The *C. davisiana* ages were estimated by matching the *C. davisiana* variations shown in Figs 2, 3 and 5 of Hays *et al.*<sup>3</sup>. The known experimental uncertainty in the TL ages is about 18%, arising primarily from the stated uncertainty in the water content. The TL age for the 342 cm sample is shown as a lower limit because it showed anomalous fading; the others did not.

travel grant from the NERC which permitted the  $\alpha$  efficiency measurements at the Research Laboratory for Archaeology, Oxford.

## Albedo contrast and glaciation due to continental drift

A POPULAR theory<sup>1,2</sup> holds that glaciation occurs when landmasses drift over the poles and cool the Earth. However, the Earth cools on balance when landmasses bunch in the tropics, rather than over the polar caps. I suggest here that a peculiar distribution of land may thus be required during glacial periods, perhaps explaining their rarity<sup>3</sup> and the long intervals when land was over the poles but the Earth was not glaciated<sup>4</sup>.

The conventional argument<sup>5</sup> assumes that the Earth cools when landmasses of variable but high albedo displace water of low albedo at the poles. While snow, which has very high albedo, is more likely to accumulate on land than on water, the first snow must fall on a 'dark' landscape. A study of the atmospheric and intrinsic determinants of surface albedo, and of the best measurements, shows that the land–water albedo contrast is greatly attenuated at the poles, and indeed is greater in the tropics, for any plausible state of affairs not involving snow.

For unidirectional radiation, received directly from the Sun, the albedo of a smooth surface is inversely proportional to  $\sin E$ , where  $E$  is the angle of elevation of the Sun<sup>6,7</sup>. Under perfectly diffuse radiation, the same surface has a different albedo, not dependent on  $E$ . The surface irradiance  $Q_*$  is never unidirectional; the atmosphere scatters the direct beam from the Sun and increases the diffuse fraction  $q_d$  of  $Q_*$ , the more so as  $E$  approaches  $0^\circ$  and the path length through the atmosphere increases. Solar radiation is never perfectly diffuse, but it is virtually so when the Sun is just below the horizon, and also under low overcasts.

As well as depending on  $E$ , the reflectivity of many surfaces varies with roughness. The choppier the sea, or the taller the plants<sup>8</sup>, the less the albedo, because multiple reflection between surface elements increases the chance of eventual absorption. Multiple reflection also reduces the albedo at high  $E$ , reinforcing the theoretical dependence mentioned above. These opposing tendencies, and that of  $q_d$  to increase at low  $E$ , make empirical facts essential.

For water the data of Grishchenko<sup>7,9</sup>, for 0–25% cloud and waves of height  $<0.7$  m, are outstanding. His albedos are much lower than those predicted for direct radiation incident on a

plane, rising from 4 to 8% at large  $E$  to a peak at  $\sim 39^\circ$  around  $E = 6$ – $8^\circ$ , then dropping to about 12–14 at  $E = 0^\circ$ . These low albedos can be taken to mean that  $Q_*$  becomes almost entirely diffuse at low  $E$ . For plant albedo, the following reliable ranges (in percentage points) are available:

- 3 (grass,  $E = 70^\circ$  to  $15^\circ$ )<sup>10</sup>
- 8 (grass,  $E = 55^\circ$  to  $10^\circ$ )<sup>7,11</sup>
- 15 (apple tree,  $E = 80^\circ$  to  $10^\circ$ )<sup>12</sup>
- 10 (Scots pine,  $E = 65^\circ$  to  $0^\circ$ )<sup>13</sup>

Tooming<sup>11</sup> found a decrease similar to Grishchenko's below  $E \approx 10^\circ$ . It seems that plant albedo varies much less with solar elevation than does water albedo.

This implies that, when the Earth is free of snow, the land–water albedo contrast is largest in low latitudes. As  $E$  decreases polewards, high-latitude waters will have albedos considerably greater than low-latitude waters, while landmasses, presumably vegetated, will increase in albedo much less towards the poles. The best way to cool the Earth in times of benign climate is therefore to place as much land as possible in the tropics.

I have tested this proposition by planimetry of land areas in  $10^\circ$  latitude belts on palaeogeographic maps<sup>14,15</sup> at 20-Myr intervals from about 240 Myr to 0 Myr. Sea level is assumed constant. These maps suffer from doubts as to the timing and geometry of drift; placement errors of the order of  $10^\circ$  (1 latitude interval) must be suspected, although their global sum will approach zero. Near the pole, albedo changes rapidly and fine resolution is desirable. I have calculated at  $10^\circ$  resolution, but have lumped the data into tropical and polar zones which are wide relative to the possible errors.

Figure 1a shows that the tropics have become much less watery in the past 80 Myr. The Earth has grown colder throughout the Cenozoic<sup>4,16</sup>, and the cooling is thought to have accelerated, just as the calculated increase in tropical landmass has. The tropical landmass has recently reached and surpassed a

**Fig. 1** a, Landmass between  $30^\circ$  N and  $30^\circ$  S; b, landmass polewards of  $60^\circ$  N and  $60^\circ$  S (both as % of total land area  $\approx 148 \times 10^6$  km<sup>2</sup>); c, world average absorbed solar radiation (equation (1)). At top of graph c, r, l stand for continental, regional and local glaciation respectively<sup>3,16,18</sup>. The age of 240 Myr data points is merely convenient; the map is dated at  $250 \pm 25$  Myr (ref. 15), and may or may not represent the early Permian glacial period. Errors of reconstruction are discussed in ref. 14; mean palaeomagnetic poles have 95% confidence limits of from  $8.7^\circ$  to  $4.5^\circ$ ; error in planimetry (sum of  $10^\circ$ -belt measurements/ $148.0 \times 10^6$  km<sup>2</sup>) on the several maps was from  $+1.6\%$  to  $-1.6\%$ .

size last attained in the Palaeozoic. Figure 1b, for comparison, shows an increase during the Cenozoic in the land surface polewards of 60° N and 60° S. Antarctica has moved little for 80 Myr<sup>15</sup> or even 100 Myr<sup>17</sup>, but it has been glaciated only since 40 Myr, with an ice-sheet since 12–15 Myr<sup>4</sup>. North-east Siberia was over or near the North Pole throughout the Triassic and Jurassic, periods for which no one has found any glacial evidence anywhere. Ice-rafted detritus is, however, found in north-east Siberia in the late Permian<sup>18</sup>. Gondwanaland was over the South Pole until ~30 Myr after the Permo-Carboniferous glacial period ended around 260 Myr<sup>3,15</sup>.

Allowing for uncertainty, either graph might account for known climatic trends. I suggest that Fig. 1a points to a new instability of the climate, underlying the widely-accepted instability of Fig. 1b.

The new instability would work as follows. When drift concentrates land in the polar caps, the tropics get wetter. Albedo contrast produces slight polar cooling and substantial warming of the tropics. On balance, the steeper polewards temperature gradient is overshadowed by the increase in world average temperature. There may be periods, such as the early Cretaceous<sup>19</sup>, of 'stable cold' limited regionally and seasonally, but global warmth is the rule, exemplified by the Mesozoic as a whole. When landmasses drift into the tropics, the caps get wetter and slightly warmer while the tropics cool substantially. Global cooling overshadows the reduced temperature gradient, and cold periods are unstable: they are more likely to intensify by the persistence of fallen snow and, for snow to persist, dry land must be suitably placed in high latitudes. This second source of instability implies that land over the poles is necessary but not sufficient for glaciation. Figure 1a and b are thus not inconsistent. Figure 1a yields a stronger necessary condition: land concentrated in the tropics as well as near the poles. By implying watery mid-latitudes, this supports ideas of the circulation required to nourish polar glaciers<sup>4</sup>.

The significance of these landmass motions can be assessed with a simple climatic model. For each 10° belt the absorbed solar radiation is

$$Q_a = (1 - \alpha) m Q_s \quad (1)$$

where  $Q_s \propto S/4$  is the incident radiation without the atmosphere<sup>20</sup>, with the solar constant  $S = 1,361 \text{ W m}^{-2}$ .  $m = Q_a/Q_s = 0.59$  is atmospheric transparency, fixed at the modern world average<sup>21</sup>. The surface albedo  $\alpha$  is a mean of land and water albedos,  $\alpha_L$  and  $\alpha_W$ , weighted by area.

$\alpha_W$  depends on latitude as follows:

Latitude	0–50	50–60	60–70	70–80	80–90
Albedo	5	6	8	10	12

with weight given to the work of Sivkov<sup>22</sup> and Grishchenko<sup>9</sup> and to the knowledge that  $q_d$  is large under clouds<sup>23</sup>.  $\alpha_L$  was chosen to be constant at 15, close to modern albedos for temperate forests<sup>24,25</sup>, marshland<sup>24</sup>, equatorial rain forest<sup>8</sup>, wet-season savanna<sup>8</sup> and tundra in summer<sup>24</sup>. Desert<sup>24</sup>, at 17–29, is the only large terrain type brighter than 15. A constant  $\alpha_L$  may seem questionable, but the argument hinges solely on a decrease in  $(\alpha_L - \alpha_W)$  with latitude. The claim is one of logic, not of numerical realism.

Placement errors affect the calculated radiation, whether or not they sum to zero, but this uncertainty is much smaller than the observed range of  $0.41 \text{ W m}^{-2}$  (Fig. 1c). A rough numerical idea of the corresponding range of temperature  $\Delta \bar{T}$  can be obtained from the expression<sup>26</sup>  $\Delta \bar{T} = k (\Delta S/S)$ , where  $\Delta S$  is a prescribed change in the solar constant and  $k \approx 140$  for several albedo-feedback models. From equation (1), making  $\Delta S$  an independent variable,  $\Delta \bar{T} \propto \Delta Q_a \approx 0.3 \text{ K}$  for the past 240 Myr. Continental drift seems a modest governor of climatic change. However, the calculations assume no snow, which is certainly unrealistic for the Cenozoic. If there is an instability, actual insolation must deviate progressively from Fig. 1c through the past 60 Myr. The absorption calculated for the present gives, when compared with the observed<sup>21</sup>  $171.5 \text{ W m}^{-2}$ , a tempera-

ture difference of 9.5 K, agreeing well with the broad average difference inferred between the present and the Mesozoic<sup>27</sup>.

When the drift sequences of the Palaeozoic are better known, more extensive tests of this work will be possible. It may have defined a stronger necessary condition for glaciation, but not its sufficiency. The idea is more firmly grounded than galactic hypotheses<sup>28</sup>; if there is a galactic mechanism, it may modulate known tectonic processes to bring about glacial periods.

I thank Trent University and the NRC of Canada for support.

## Hidden genetic variability in two populations of a marine mussel

ELECTROPHORESIS detects only about one third of the genetic variation present in a natural population, despite its wide application<sup>1</sup>. A combination of electrophoretic and heat denaturation techniques has revealed considerable molecular variation within single electrophoretic classes of enzymes. For example, Bernstein *et al.*<sup>2</sup> have found 1.74 more alleles at the xanthine dehydrogenase locus in the *Drosophila virilis* group than had been detected by electrophoresis alone. Further such evidence<sup>3–11</sup> has concentrated on species of *Drosophila*. I report here a study of the marine mussel *Guekensia demissa* (formerly *Modiolus demissus*) which shows that in two geographically separated populations experiencing different temperature regimes, there is an apparent correlation between the distribution of thermosensitive alleles at the phosphoglucosylase (*Pgm*) locus and environmental temperature.

Samples of *G. demissa* were collected from a salt marsh at Beaufort, North Carolina (35° N) and from the intertidal region of a beach at Stony Brook, Long Island, New York (41° N). Water temperatures in the Beaufort region can reach a summer maximum of 33 °C while in Long Island Sound they rarely reach 28 °C. Air temperatures in both regions are correspondingly higher<sup>12</sup>.

**Table 1** Distribution of genotypes and allele frequencies at the *Pgm* locus in two populations of *Guekensia demissa* from Beaufort and Stony Brook

	N*	AA	BB	Genotypes					Allele frequency				$\chi^2$
				CC	AB	AC	BC	BD	A	B	C	D	
Beaufort	103	9	22	5	29	17	20	1	0.31	0.46	0.23	0.01	0.61NS
Stony Brook	51	4	9	6	9	6	17	—	0.23	0.43	0.34	0.0	0.49NS

\* Number of individuals analysed.

 $\chi^2$ , Goodness-of-fit of observed to expected frequencies from Hardy-Weinberg equilibrium.NS,  $P > 0.05$ .**Table 2** Distribution of genotypes and allele frequencies at the *Pgm* locus in two subsamples of *Guekensia demissa* from Beaufort and Stony Brook retained for heat stability studies

	N	AA	BB	Genotype					Allele frequency				$\chi^2$
				CC	AB	AC	BC	BD	A	B	C	D	
Beaufort	39	5	8	3	10	6	6	1	0.34	0.42	0.23	0.01	1.43NS
Stony Brook	40	5	7	6	7	3	12	—	0.25	0.41	0.34	0.0	4.47NS

In *G. demissa* *Pgm* is coded at a single locus, with three common alleles *Pgm*<sup>A</sup>, *Pgm*<sup>B</sup> and *Pgm*<sup>C</sup> present in both populations, and a rare allele *Pgm*<sup>D</sup> detected only in the Beaufort sample. Two procedures were initially used to evaluate the thermostability of these *Pgm* alleles. First, two aliquots of a homogenate of adductor muscle from a single individual were incubated at two temperatures, followed by electrophoresis and staining; second, slices of a starch gel were incubated at two temperatures after electrophoresis of a homogenate of adductor muscle from a single individual, followed by the addition of *Pgm* stain. Temperature and duration of incubation were decided empirically. Heat stability studies were performed using the first procedure in preference to the second because conditions could be controlled more easily.

Table 1 presents allele frequency data for the two samples of mussels. The samples were similar in allele frequency and no significant departures from Hardy-Weinberg expectations were observed. No significant differences in either genotypic ( $P = 0.20$ ) or allelic ( $P = 0.07$ ) proportions were observed when the two samples were compared. Smaller numbers of individuals within each of these samples were used for thermostability studies and Table 2 gives allele frequency data for these subsamples. Allele frequencies were similar to those observed in Table 1, with no significant departures from Hardy-Weinberg equilibrium. In addition, no significant differences in either genotypic ( $P = 0.52$ ) or allelic ( $P = 0.28$ ) proportions were observed between the two smaller samples.

A *Pgm* band was classified as being either heat-resistant (in this case *Pgm* activity present after 15 min at 60 °C) or heat-sensitive (no *Pgm* activity after 15 min at 60 °C). Two kinds of

homozygotes were observed: those in which the *Pgm* band was either heat-sensitive or heat-resistant. Four kinds of heterozygotes were observed: those in which both *Pgm* bands were heat-sensitive or heat-resistant and those in which one or other of the *Pgm* bands was heat-sensitive (Fig. 1). This suggests that heat-sensitivity of each *Pgm* electrophoretic band resides at the level of the *Pgm* structural gene. Table 3 presents allele frequency data for the two populations when electrophoretic and heat-sensitivity determinations were combined. Both heat-sensitive and heat-resistant forms of the alleles *Pgm*<sup>A</sup>, *Pgm*<sup>B</sup> and *Pgm*<sup>C</sup> were observed in the two samples of mussels. In the Beaufort sample, where *Pgm*<sup>D</sup> was observed at low frequency, only the heat-sensitive form of *Pgm*<sup>D</sup> was detected. This newly discovered variation increases heterozygosity values (calculated from observed allelic frequencies) for this locus from 0.66 to 0.73 in the Beaufort sample and from 0.65 to 0.79 in the Stony Brook sample. Sixty-eight of the 78 alleles investigated in the Beaufort sample were heat-resistant and in the Stony Brook sample 56 of the 80 alleles investigated were heat-resistant. Analysis was performed on these numbers using a  $2 \times 2$  contingency  $\chi^2$  test and the distribution of heat-sensitive and heat-resistant *Pgm* alleles was found to be significantly different in the two populations ( $0.01 > P > 0.001$ ). The frequency of heat-sensitive forms of the three major alleles was consistently higher (particularly for *Pgm*<sup>B</sup>) in the sample of mussels from the cooler waters of Long Island Sound. Also, the frequency of individuals homozygous for resistant alleles was significantly greater ( $0.05 > P > 0.02$ ) in Beaufort (31 out of 39 individuals) than in Stony Brook (23 out of 40 individuals) and the frequency of individuals homozygous for sensitive alleles was greater in Stony

Superscript s and r correspond to heat-sensitive and heat-resistant forms of *Pgm* alleles.

**Fig. 1** Heat sensitivity of *Pgm* alleles in *Guekensia demissa*. (Results of two gels from the same electrophoretic run; gel papers were divided and transposed to eliminate repetitive patterns.) The posterior adductor muscle was excised from living individuals and homogenised manually in approximately two volumes of 50 mM Tris-HCl buffer, pH 7.8 (1:1 w/v). Homogenates were centrifuged at 3,500 r.p.m. for 15 min at 4 °C. The supernatant solution was divided into four aliquots, two of which were incubated in a water bath for 15 min, one at 37 °C and the other at 60 °C. The remaining two aliquots were retained for replication; hence each individual was classified on the basis of two replicated experiments. Electrophoresis was performed at 2 °C in horizontal starch gel (Electrostarch) using the Tris-EDTA-maleic buffer system, pH 7.4, of Spencer *et al.*<sup>13</sup>. Gels were run for 14–16 h at 6.5 V cm<sup>-1</sup>. Sliced gels were stained for *Pgm* using the paper overlay method described by Scopes<sup>14</sup>. The terminology used for allozymes of *Pgm* is as follows: alleles are numbered A to D in order of increasing anodal mobility. For comparative purposes individuals from both populations were run on the same gel.

Brook (7 out of 40 individuals) than in Beaufort (2 out of 39), although this difference is not significant at the 5% level ( $0.10 > P > 0.05$ ).

In spite of increasing experimental evidence for hidden genetic variability within electrophoretic allozyme classes—at least for species of *Drosophila*—there have been no reports to date on the possible biological significance of this new-found structural variability. Some workers<sup>2,5</sup> commenting on the random distribution patterns of some of the heat-sensitive allozymes of xanthine dehydrogenase and octanol dehydrogenase in the *Drosophila virilis* group concluded that such patterns support the neutral and not the selection hypothesis of genetic variability in natural populations. It is possible that the apparent non-random distribution of thermosensitive alleles in the mussel populations investigated in the present study is being maintained through selective forces acting at the *Pgm* locus. Trippa *et al.*<sup>9</sup> have suggested 'that selective values of allelic proteins with different thermosensitivities might in fact be affected by differences in the habitat', perhaps in this case temperature, an important component of an organism's environment. However, before firm conclusions can be drawn regarding the adaptive role of hidden genetic variation within populations of *G. demissa*, detailed biochemical investigations of the *Pgm* system are necessary. Also, breeding data—at present unavailable—would clarify whether the property of thermosensitivity is associated with the *Pgm* locus itself or whether it is associated with an alternative polymorphic locus.

I thank Noel Wilkins, J. Bolling-Sullivan and Roger Milkman for their help, and John Costlow, Duke Marine Laboratory, and the National Board of Science and Technology, Ireland for financial support. I also thank Jeffrey Levinton for collecting the Stony Brook sample of mussels. Temperature data were supplied by the Marine Information and Advisory Service (UK).

## Mutation at H-2K locus influences susceptibility to autoimmune thyroiditis

GENES in the major histocompatibility complex (MHC) have been found to be associated with the development of autoimmune diseases, including spontaneous diseases in man<sup>1,2</sup> and spontaneous<sup>3</sup> or experimentally induced autoimmunity in animals<sup>4</sup>. Experimental autoimmune thyroiditis (EAT) can be induced in susceptible strains of mice, such as those with the MHC H-2<sup>k</sup> haplotype, by injecting them with mouse thyroglobulin together with complete Freund's adjuvant<sup>5</sup>. In contrast, injection of mice homozygous for the H-2<sup>b</sup> haplotype fails to induce the mononuclear cell infiltration of the thyroid gland characteristic of EAT. We report here that susceptibility to induction of EAT results from an apparent point mutation which evidently occurred at the H-2K locus of the resistant H-2<sup>b</sup> haplotype. This indicates that the H-2K glycoprotein can serve to regulate the autoimmune response to thyroglobulin.

Table 1 shows the results of injecting mouse thyroid extract in adjuvant into mice of strains C3H/eb (H-2<sup>k</sup>), C57BL/6 (H-2<sup>b</sup>) or its HZ1 mutant (B6.C-H-2<sup>ba</sup>)<sup>6,7</sup>. C3H/eb mice demonstrated the response of high-responder H-2<sup>k</sup> strains with about 80% incidence of development of EAT. Only about 20% of C57BL/6 mice developed lesions of EAT, as expected for low responder mice of H-2<sup>b</sup> strains<sup>5,8</sup>. However, the HZ1 (H-2<sup>ba</sup>) mutant showed an incidence of EAT (79%) comparable with that of high-responder H-2<sup>k</sup> mice. Hence, the HZ1 mutation led to susceptibility to EAT in mice whose original genome coded for resistance.

The immunogen used in these experiments was thyroid extract obtained from C3H/eb mice. Mouse strains differ in the immunogenicity of their thyroglobulin<sup>9</sup> and we have found that thyroid extract from C3H/eb mice is strongly immunogenic whereas that of both C57BL/6 and HZ1 mice is poorly immunogenic for either high- or low-responder strains of mice (in preparation). These findings suggest that the increased

**Table 1** Susceptibility to EAT of the HZ1 mutant (H-2<sup>ba</sup>), and H-2<sup>b</sup> low- and H-2<sup>k</sup> high-responder strains of mice

Mouse strain	H-2 haplotype	Injection of thyroid extract plus adjuvant	Incidence of EAT	Antibody titre (log <sub>2</sub> )
C3H/eb	k	Yes	82% (46/56)	5.0
C57BL/6	b	Yes	20% (10/49)	5.0
HZ1	ba	Yes	79% (11/14)	7.0
		Adjuvant alone	0 (0/5)	<1.0

Mice were injected twice subcutaneously at 7-d intervals with thyroid extract emulsified in complete Freund's adjuvant, as described by Twarog and Rose<sup>21</sup>. The extract was prepared from thyroid glands of C3H/eb mice. Each mouse received the equivalent of one thyroid gland. The adjuvant<sup>21</sup> was prepared by adding 7 mg ml<sup>-1</sup> of *Mycobacterium tuberculosis* H37Ra (Difco) to incomplete Freund's adjuvant (Difco). The animals were killed 5 weeks after the second injection and histological sections of the thyroid glands were examined in a blind fashion by two independent observers. A thyroid gland was considered to be positive for EAT if it showed at least one unequivocal focal infiltrate of mononuclear cells<sup>9</sup>. Antibodies to purified thyroglobulin, prepared as described by Tomazic and Rose<sup>9</sup>, were measured in the pooled serum of mice in each group, using a haemagglutination of formalinised tanned sheep red blood cells<sup>22</sup> coated with thyroglobulin. The results represent three separate experiments. Difference in incidence of EAT between C57BL/6 and HZ1 was highly significant by the  $\chi^2$  test ( $P < 0.0003$ ).

incidence of EAT in the HZ1 mutant mice was not due to a change in the immunogenicity of their thyroglobulin.

Note that all groups developed antibodies to purified thyroglobulin after injection with thyroid extract in adjuvant. This confirms the observation that mice develop specific antibodies to determinants of thyroglobulin after injection with extract, whether or not they are genetically susceptible to histological EAT<sup>10</sup>.

The HZ1 mutant has been studied in several laboratories<sup>7,11-14</sup> and it is generally concluded that a point mutation occurred at the H-2K locus of the C57BL/6 genome. This conclusion is supported by the finding of differences in the peptide map of the H-2K glycoprotein of the HZ1 mutant, compared with the wild-type C57BL/6 strain<sup>15</sup>. This molecular difference would seem to account for the mutual T-cell reactivity of C57BL/6 and HZ1 (refs 13, 16). However, the HZ1 mutant seems to preserve other determinants on the H-2K molecule which are identical to those of the H-2K<sup>b</sup> wild type<sup>7,12</sup>.

There is no evidence of any differences between C57BL/6 and HZ1 in the I region to the right of the H-2K locus, as the immune response (Ir) genes which functionally define the I region are the same in the mutant and wild-type mice<sup>17</sup>. Thus, it seems very likely that the only genetic differences between the wild-type C57BL/6 and the HZ1 mutant mouse are at the H-2K locus of the MHC<sup>7</sup>. Hence, our results indicate that the H-2K glycoprotein can regulate the pathological expression of EAT following an autoimmune response to thyroglobulin. This implies a major role for cytotoxic T cells in EAT. Furthermore, the limited portion of the H-2K<sup>b</sup> gene in which the mutation occurred, the Z1 locus<sup>6</sup>, seems to be critical in determining susceptibility to EAT.

Previously, H-2K or H-2D gene products have been observed to restrict the cytotoxic effects of T lymphocytes against target cells infected with certain viruses<sup>18</sup>. T lymphocytes obtained from mice immunised against viruses will often kill virus-infected target cells only when the target cells and the lymphocytes have H-2K or H-2D genes in common. Note that HZ1 and C57BL/6 differ in the specificity of virus-H-2K-associated cytotoxicity<sup>13</sup>. It is thought that associative recognition by T lymphocytes of viral antigens together with MHC gene products is based on the molecular association of viruses with MHC gene products at the surface of the infected cell<sup>19,20</sup>. It remains to be determined whether susceptibility to EAT also

involves physical association between H-2K glycoprotein and thyroglobulin on the surface of thyroid epithelial cells. Such an association could occur if MHC gene products served to control movement of macromolecules across cell membranes.

The different susceptibilities to induction of EAT of the C57BL/6 strain and its HZ1 mutant suggest that these mice may be helpful in determining how MHC gene products regulate immune responses. Any differences between the mice in the handling or presentation of thyroglobulin by macrophages, lymphocytes or other cells could be related to the specific modification of the H-2K glycoprotein. Furthermore, isolation of purified H-2K glycoproteins may allow study of the interaction of these molecules with specific determinants of thyroglobulin.

## A novel subset of antigenic cells triggers B-cell responses to MHC antigens

THE exceptional immunogenicity of major histocompatibility complex (MHC) antigens is well known but poorly understood. As there is evidence that MHC products are intimately involved in the presentation of antigen to T cells<sup>1,2</sup> it seems reasonable to expect that antigenic variants of these 'presenting structures' should be very immunogenic for T cells. However, because MHC antigens on non-nucleated cells and in subcellular forms are weak T-cell immunogens and may even function as tolerogens<sup>3</sup>, it has been postulated that an additional signal from living antigenic cells is needed to stimulate the immune response<sup>4</sup>. The response of B cells to MHC antigens is far less well understood but again an additional signal from antigenic cells seems to be needed in some primary responses, as antigenic cell fragments are not immunogenic<sup>5</sup>. We report here that in studies of primary antibody responses to H-2-incompatible cells, immunogenicity is almost completely restricted to a small, novel subpopulation of cells found in the spleen and bone

**Table 1** For induction of primary anti-H-2 PFC responses conventional T-cell competence in donors and recipients is not required

Experiment	Recipient strain	Donor strain	Dose of donor spleen cells	PFC per spleen Mean (s.e.m.)
1	CBA	B10 <i>nu/+</i> and <i>+/+</i>	$2 \times 10^6$	936 (155)
	CBA	B10 <i>nu/nu</i>	$2 \times 10^6$	2,136 (139)
2	<i>nu/+</i> and <i>+/+</i>	B10 <i>nu/nu</i>	$10^6$	1,800 (278)
	<i>nu/nu</i>	B10 <i>nu/nu</i>	$10^6$	2,730 (449)
3	<i>nu/+</i> and <i>+/+</i>	BALB/c	$10^7$	14,866 (4,050)
	<i>nu/nu</i>	BALB/c	$10^7$	8,370 (2,773)
4a	<i>nu/nu</i>	BALB/c <i>nu/nu</i>	$2.3 \times 10^6$	40,577 (8,452)
	<i>nu/+</i> and <i>+/+</i>	BALB/c <i>nu/nu</i>	$2.3 \times 10^6$	10,450 (3,215)
4b	<i>nu/nu</i>	BALB/c <i>nu/+</i> and <i>+/+</i>	$2.3 \times 10^6$	26,717 (6,331)
	<i>nu/+</i> and <i>+/+</i>	BALB/c <i>nu/+</i> and <i>+/+</i>	$2.3 \times 10^6$	21,008 (4,944)

Anti-H-2<sup>b</sup> responses were determined in experiments 1 and 2 and anti-H-2<sup>d</sup> responses in experiments 3 and 4. PFC were assayed by the technique developed by Fuji *et al.*<sup>6</sup> and modified from our method for assay of anti-Thy-1 PFC<sup>12</sup>. Briefly, 50  $\mu$ l of appropriate concentrations of spleen cells in Eagle's modified minimal essential medium (MEM) containing 10% heat-inactivated newborn calf serum (MEM+CA<sub>10</sub>) were mixed with 20  $\mu$ l of 20–40% (packed volume) of appropriate target cells. The suspension was warmed to 37 °C and 180  $\mu$ l of 1% agarose in MEM-CA<sub>10</sub>, kept at 45–48 °C, was added immediately before pouring on to 30-mm Petri dishes. These plates were incubated at 37 °C in a humidified 10% CO<sub>2</sub> atmosphere for 3.5 h, and then an anti-mouse Ig, rabbit antiserum (0.5 ml at 1:10) was added. Following a further incubation at 37 °C for 30 min 1.0 ml of selected rabbit complement at 1:15 dilution (in 10% hypotonic MEM-CA<sub>10</sub> containing 3 mM barbituric acid) was added. After 45 min incubation with complement, these plates were stained with 0.2–0.3% of Trypan blue in phosphate-buffered saline for 15 min. The numbers of plaques were counted with the aid of a dissecting microscope. Almost all PFC detected by this technique were IgM-secreting cells, as addition of a specific anti- $\mu$  serum (20  $\mu$ l of 1:60 dilute antiserum) into the mixture of spleen cells and target cells before incubation inhibited the development of plaques. Primary PFC responses assayed on day 5 are shown.

marrow. Furthermore, as the response we have studied is independent of T cells, these stimulating cells seem to be unique (perhaps specialised?) in their ability to present surface-borne antigen and the additional signal to responding B cells.

The experimental system was developed from the anti-H-2 direct plaque-forming cell (PFC) assay of Fuji *et al.* in which specificity for H-2K and H-2D region antigens has been established and other parameters of response have been defined<sup>6,7</sup>; these findings have since been confirmed in our laboratory (in preparation). Primary responses to H-2 antigens were induced by intraperitoneal injection of spleen cells into appropriate recipients. Spleens of responding mice were removed after 5 days, at the peak of response, and their content of PFC determined in the plaque assay using the lymphoma lines L1210(H-2<sup>d</sup>) or EL-4G<sup>-</sup>(H-2<sup>b</sup>) as targets.

To examine the role of T cells in the response, normal or T-cell deficient mice were immunised with antigenic spleen cells from normal or T-cell deficient donors. The response of CBA mice to spleen cells from C57BL/10 or C57BL/10 *nu/nu* donors (H-2<sup>b</sup>) shows that T-deficient cell populations may in fact provoke stronger responses than C57BL/10 *nu/+* control donor mice, which have a normal T-cell compartment (Table 1). Thus, T cells in the inoculum are apparently unnecessary for the induction of primary PFC in these conditions. Using outbred *nu/nu* and littermate *+/+* and *nu/+* recipients in combination with C57BL/10 *nu/nu* donors it is apparent (Table 1) that T-cell deficient recipients respond equally well or better than their controls to C57BL/10 *nu/nu* donors. Similarly, the response to H-2<sup>d</sup> antigens is also substantially independent of T cells in the donor or in responding mice (Table 1, experiments 3, 4). Thus, conventional T-cell functions seem to have no role in the primary PFC response to H-2 antigens.

These results significantly strengthen previous evidence that primary responses to MHC antigens of mice (and rats) are mainly independent of conventional T-cell activity<sup>8,9</sup>. It is, however, unexpected that glycoproteins such as MHC antigens

should induce substantial T-cell independent responses. First, their physical properties are at marked variance with properties common to other T-cell independent antigens, such as a polymeric molecular structure and slow catabolism *in vivo*<sup>10</sup>. Second, and in contrast to H-2, we have shown that the primary PFC response to another glycoprotein surface antigen, Thy-1, is dependent on T-cell mediated helper effects produced by other surface antigens coded elsewhere in the donor genome<sup>11–13</sup>. Taken together, these apparently contradictory observations suggest that the molecular and antigenic properties which determine the immunogenicity of cell-surface antigens cannot be predicted from present knowledge and are likely to be quite different from those for molecular antigens in solution.

In further experiments, to be reported in detail elsewhere, we found that some lymphoid tissues were markedly more immunogenic than others (for example, spleen cells are approximately 20 times more active at stimulating PFC than lymph node cells, and unfractionated peritoneal cells are virtually inactive). However, the density of H-2 antigens as determined by absorption tests was indistinguishable in the different cell populations. We therefore postulated that immunogenicity for primary PFC may not be related simply to the amount of H-2 antigen on the donor cell inoculum but could reside in an immunogenic subpopulation of cells which is present in higher frequency in the spleen. To examine this possibility donor spleen cells were fractionated with respect to (1) adherence to nylon

**Table 2** Characterisation of spleen cells immunogenic for primary anti-H-2 PFC

Experiment (recipient strain)	Donor pre-treatment	Fractionation Adherence	Density	Cell recovery (%)	Dose of viable cells	PFC per spleen
1. (CBA)		Unseparated		100	$2 \times 10^6$	2,136
		Adherent		31 (55)	$2 \times 10^6$	900
		Non-adherent		22 (45)	$2 \times 10^6$	5,028
2. (CBA)		Unseparated			$1 \times 10^6$	1,356

		Irradiation Non-adherent	High		$5 \times 10^3$	315
		Irradiation Non-adherent	High		$5 \times 10^4$	13,812

The results show that the immunogenicity belongs to a small subset of cells which is relatively non-adherent to nylon wool, of unusually high density, and resistant to irradiation administered *in vivo*. Donor BALB/c mice were irradiated at 900 R from a <sup>60</sup>Co source 20 h before removal of spleens. For fractionation, 1 ml of an appropriate concentration ( $5 \times 10^7$  ml<sup>-1</sup>) of spleen cells from normal or irradiated BALB/c mice in MEM containing 5% fetal calf serum (MEM-F<sub>5</sub>) were loaded on nylon wool columns each of 0.6 g in a 6-ml volume. Nylon-non-adherent cells were eluted after incubation of the columns at 37 °C for 1 h by the procedure of Julius *et al.*<sup>22</sup>. Nylon-adherent cells were also collected after thoroughly washing the columns according to the method of Trizio and Cudkovic<sup>23</sup>. Five ml of the suspension of nylon-non-adherent cells ( $< 10^7$  p/ml<sup>-1</sup>) were layered on 3 ml of Ficoll-Hypaque solution ( $\rho = 1.082$ ) and centrifuged at 3,000 r.p.m. for 20 min at 20 °C. The pellet fraction (high-density fraction) and interface fraction (low-density fraction) were collected and washed three times with MEM at 150 g for 8 min. Day 5 primary PFC responses are shown. Each value represents the mean of five mice. The standard error of each value is less than 25%, except the values marked with an asterisk ( $\geq 25\%$ ). Donor cells for experiment 4 were irradiated *in vitro* at 2,000 R before injection. Cell recovery is given as the percentage of recovery of cells in each fraction to overall recovery of cells after fractionation.

† Treated with 0.83 M ammonium chloride to lyse erythrocytes before injection.

**Table 3** Ability of spleen cell fractions to stimulate PFC to H-2 antigens does not correlate with their stimulatory ability in MLC

Cell fraction	Buoyant density	MLC		PFC per spleen
		c.p.m.	Index	
Nylon-adherence				
Original		65,112	5.3	
Adherent	—	45,748	3.7	225 (61)
Non-adherent	—	29,040	2.3	
Non-adherent	Low	43,972	3.6	0 (0)
Non-adherent	High	7,854	-0.6	32,364 (6,990)
(Syngeneic control)		12,264	1.0	

For MLC,  $6 \times 10^5$  CBA spleen cells in 0.1 ml of RPMI medium containing 10 mM HEPES,  $5 \times 10^{-5}$  M 2-mercaptoethanol and 5% heat-inactivated fetal calf serum were mixed with  $6 \times 10^5$  CBA spleen cells (syngeneic control) or BALB/c spleen cells which had been fractionated and irradiated at 2,000 R. They were incubated in a humidified, 10% CO<sub>2</sub> atmosphere at 37 °C for 5 d, and then pulsed with 1  $\mu$ Ci of [<sup>125</sup>I]5-iodo-2'-deoxyuridine. After 4 h incubation the cultures were collected on filter paper for counting. MLC results are the mean of three to four cultures. PFC results are day 5 primary anti-H-2 PFC responses of B10 mice injected with  $10^5$  cells. This is part of experiment 4 in Table 2. Values represent mean PFC (s.e.m.).

wool, (2) buoyant density and (3) resistance to  $\gamma$ -irradiation administered *in vivo* 1 day before the donors were killed. It is clear from results using nylon wool columns (Table 2, experiments 1, 2, 4, 5, and Table 3) that on comparing inocula of viable cells, the immunogenic cells are enriched in the non-adherent fraction and significantly depleted in the adherent fraction. Subsequent fractionation of the non-adherent cells on Ficoll-Hypaque (density 1.082 g cm<sup>-3</sup>) showed that immunogenic cells are enriched in the dense fraction (the pellet) and virtually absent in the lymphoid cell-rich, interface buoyant fraction (Table 2, experiments 2-5, and Table 3).

The radiosensitivity of the immunogenic cell fraction was assessed by irradiation of donors with 900 R from a <sup>60</sup>Co source 20 h before removal of their spleens. It is evident (Table 2, experiment 5) that spleen cells from irradiated donors are considerably more immunogenic than similar numbers of normal spleen cells. Further fractionation of this irradiated population of nylon wool columns resulted in decreased immunogenicity in the adherent cell fraction, as before. The non-adherent fraction was separated on Ficoll-Hypaque and showed, also as before, no immunogenicity of the interface cells but very high immunogenicity of the dense fraction. The factor of enrichment for the subpopulation of immunogenic cells with the three procedures in combination is estimated to be 50- to 70-fold. The data presented above, together with the unusual tissue distribution of the immunogenic cells, their presence in nude mice, the results of the fractionation procedures and some unpublished results, make it unlikely that the immunogenic cells are conventional T, B or macrophage-like cells. Furthermore, cells of the granulocytic series which are usually enriched in high-density fractions are highly radiosensitive and adherent to nylon, as confirmed by microscopic observation.

Recent evidence indicates that specialised accessory cells are highly efficient in the presentation of antigen to T cells<sup>14</sup>, and these cells are the most active in stimulating allogenic responses in mixed leukocyte cultures (MLC)<sup>15</sup>. As the MHC antigens on the non-adherent, dense cells stimulated B cells to produce PFC in our experiments, we also examined the ability of these cells to stimulate T cells in MLC<sup>16</sup>. As shown in Table 3 no correlation was observed between cell fractions which stimulated in MLC and those which stimulated PFC in the same experiment. In fact, the non-adherent high-density fraction, which is by far the most effective in inducing PFC, reproducibly induced little or no MLC. This result, taken with the other physical parameters considered above, seems to distinguish the novel PFC-stimulating fraction from the cells considered to be functionally specialised for antigen presentation to T cells<sup>14,15,17</sup>.

The normal role of these B-stimulating cells in the immune system is unknown but their unusual properties should facilitate investigation. However, *in vitro* studies show that accessory cells or antigen-presenting cells are involved in B-cell triggering for

T-cell dependent<sup>18</sup> and possibly some T-cell independent responses<sup>19-21</sup>. Such cells may be identical to the antigen-presenting cells for T-cell responses or may comprise a new subpopulation of cells. The novel subset of cells reported here to be exceptionally immunogenic for B cells may have a role in antigen presentation and B-cell triggering.

We thank Professor N. A. Mitchison for advice and Ms Susan Edwards for technical assistance.

## CFU-S in individual erythroid colonies derived *in vitro* from adult mouse marrow

It is generally accepted that in the haematopoietic system there is a hierarchy of pluripotent and committed progenitor cell types. Representative committed progenitors from all the myeloid and lymphoid pathways can be detected by *in vitro* colony assays<sup>1</sup>. This methodology has been extended to include multipotent haematopoietic progenitors<sup>2-5</sup>, and it has since been shown that at least one such multipotent cell type, the progenitor of macroscopic erythroid-megakaryocyte bursts, undergoes self-renewal during colony formation *in vitro*<sup>5</sup>. We now report that cells capable of macroscopic spleen colony formation (CFU-S)<sup>6</sup> are present in macroscopic bursts and that on average two to three and up to five self-renewal divisions of CFU-S can occur during the first 9 d of burst growth. These findings raise the possibility that clonal analysis techniques<sup>7</sup> may be combined with cell culture manipulations to investigate how the choice between self-renewal and progressive differentiation is determined.

Macroscopic bursts were generated in standard methylcellulose cultures containing 2.5 units ml<sup>-1</sup> erythropoietin (Connaught, Step III) and pokeweed mitogen-stimulated spleen cell conditioned medium (final concentration 0.3%) as previously described<sup>5</sup>. These conditions are optimal for macroscopic burst formation and give a linear relationship between

**Fig. 1** Burst formation as a function of the number of cells plated. Cells were pooled from three replicate 2-week-old flask cultures maintained and assayed as described in the text. The number of cells in each assay dish is expressed as a fraction of the total number of non-adherent cells collected per flask. In this experiment 1/100th of a flask contained  $6.4 \times 10^4$  cells. Values shown represent the mean count  $\pm 1$  s.e.m. for a minimum of four assay replicates.

burst number and cell concentration (Fig. 1). They are inadequate for significant granulocyte colony formation. The cells used for plating were from the non-adherent cell fraction of 2-week-old flask cultures prepared using adult B6C3F<sub>1</sub> mouse marrow cells as previously described<sup>8,9</sup>. Although cells capable of macroscopic burst formation are present in fresh as well as cultured adult marrow, their incidence in fresh marrow is much lower (only 5–10 per  $10^5$  nucleated cells) and they constitute less than one-third of the total late-maturing burst progenitor population<sup>5</sup>. In the conditions of flask culture used here, there is a preferential proliferation and survival of macroscopic burst progenitors so that by 2 weeks their concentration reaches 30–50 per  $10^5$  nucleated cells and they constitute the predominant erythropoietic cell type<sup>5,8</sup>. Thus, by plating  $2.5 \times 10^4$  flask cultured cells (that is, 1/200th of a flask, washed and diluted in  $\alpha$ -medium plus 2% fetal calf serum) 10–20 well isolated macroscopic bursts were obtained in each assay dish (Fig. 1), and the problem of contaminating background colonies derived from either granulopoietic progenitors (CFU-C) or more mature erythropoietic progenitors (day 14 BFU-E micro, day 3 BFU-E, CFU-E) was also eliminated. After 9 d of incubation, macroscopic bursts could be readily identified as red spots visible to the unaided eye (Fig. 2a). Such bursts were picked and assayed for CFU-S (see Table 1 legend for details). Macroscopic spleen colony counts were carried out on day 9 (Fig. 2b).

Of 25 macroscopic bursts assayed individually, 11 (44%) produced spleen colonies (Table 1a). On average each produced one spleen colony although values of up to four were obtained. The incidence of approximately one CFU-S per macroscopic burst was confirmed when suspensions consisting of four or eight pooled macroscopic bursts were assayed, and the proportion of pools that were positive increased to 78% and 87%, respectively. The wide distribution of values obtained for different pools of four and even eight bursts also confirms the heterogeneity seen when individual bursts were assayed. Presumably, some of the macroscopic bursts contained at least four times the overall average number of CFU-S. Using an estimate of 0.15 for

the seeding fraction ( $f$ )<sup>10</sup>, the total CFU-S per macroscopic burst was on average 6.7 and must have reached at least 27 in some bursts. This would indicate an average of two to three, and up to five self-renewing cell divisions.

Spleen colony formation was not associated with a cell type that occurred randomly throughout the burst assay culture, for aliquots of 'background' culture equivalent to three times the culture volume contained in a pool of eight macroscopic bursts did not produce spleen colonies (Table 1a). Irradiation of the injected cells also eliminated spleen colony formation (Table 1b). In addition, karyotype analysis of metaphases in female recipient spleens removed 10 d after irradiation and injection with male macroscopic bursts showed 33 of 37 metaphases to be of male, that is, burst cell, origin (of the remaining four metaphases, three were scored as probable males and one as female). For this analysis three spleens with visible surface colonies were made into single cell suspensions 1–2 h after intraperitoneal injection of 50  $\mu$ g colcemid. Metaphase spreads were C or trypsin G-banded and a sample of technically suitable metaphases photographed and evaluated by P.J. and F.D. for 40 chromosomes and the Y chromosome<sup>11</sup>. These results indicate that the spleen colonies obtained resulted from proliferation of cells originally present in macroscopic bursts.

Previous experiments with macroscopic bursts have suggested a close relationship between their progenitors and CFU-S<sup>5</sup>. The present findings provide direct evidence for overlap between the cell populations detected by these two assays. Further experiments will be required for full characterisation of the *in vivo*

Using an inverted microscope, 9-d-old isolated macroscopic bursts were selected and taken up individually into a sterile, finely drawn out Pasteur pipette containing a small quantity of  $\alpha$ -medium. Care was taken to remove each burst in the smallest volume possible (by weighing dishes this was determined to be no more than 1/250th of the total 1.0-ml culture volume) to minimise further any possible contamination with extraneous cells. The required number of macroscopic bursts were placed in a small volume of  $\alpha$ -medium on ice and a single cell suspension obtained by gentle aspiration through a no. 21 needle before injection through a no. 26 needle. B6C3F<sub>1</sub> recipient mice were given 850 rad whole-body radiation<sup>5</sup> followed by up to 0.6 ml of test material injected into the tail vein. For background values aliquots containing 10% of the culture volume (0.1-ml volumes) were picked at random under microscopic visualisation avoiding only macroscopic bursts and other large colonies ( $>100$  cells). This volume represents 3 $\times$  that picked for assays of eight macroscopic bursts and 24 $\times$  that picked for assays of single bursts. S.e.m.s were calculated by pooling data from expts 1–4. b In exp. 5, 8 separate pools, each containing 16 macroscopic bursts, were prepared. Each pool was then subdivided equally between two mice. One of these had already been given 850 rad whole-body X-irradiation before injection in the normal fashion. The other was not irradiated until immediately after injection so that in this group both the cells to be assayed and the recipients were exposed to the same 850-rad treatment. In exp. 6, 4 separate pools, each containing 16 macroscopic bursts, were prepared. Half of each pool was divided and assayed for CFU-S in two recipients in the usual fashion. The other half of each pool received 1,000 rad (X ray) *in vitro* before being divided and assayed for CFU-S in two recipients. ND, not determined.

repopulating and differentiative potentialities of cells derived from macroscopic burst progenitors.

The broad distribution of CFU-S numbers in individual bursts is of interest, as it approaches that observed for CFU-S self-renewal in spleen colonies<sup>10,12</sup>. The number of cells plated in burst assay cultures was low. It thus seems most likely that the distribution observed was due to statistical fluctuations<sup>13</sup> rather than micro-environmental influences<sup>14</sup>. This does not negate the possibility that in complex cell systems, stem cell growth and differentiation can be locally influenced by other cell types in the immediate vicinity. It does, however, suggest that their effects can be studied using soluble factors. The high frequency of CFU-S per burst demonstrated here is an order of magnitude higher than that recently reported for mixed haematopoietic colonies of early fetal liver cell origin<sup>15</sup>. Thus, experiments to analyse the progeny of individual adult marrow stem cells stimulated *in vitro* are now possible. An immediate application will be to study the possible influence of various molecular factors on the self-renewal and differentiative behaviour of these stem cells.

## Evidence that substance P does not mediate slow synaptic excitation within the myenteric plexus

ELECTRICAL stimulation of presynaptic fibres to the so-called AH<sup>1</sup> or type II<sup>2</sup> myenteric neurones in guinea pig small intestine evokes a slow excitatory postsynaptic potential (e.p.s.p.) characterised by long-lasting depolarisation associated with increased membrane resistance and augmented excitability<sup>3</sup>. Two substances have been implicated as possible neurotransmitters for the slow e.p.s.p. Katayama and North reported that application of substance P to myenteric neurones mimicked the slow e.p.s.p.<sup>4</sup>, and J.D.W. and C.J.M. presented several lines of evidence for serotonin as the transmitter substance<sup>5,6</sup>. We now report that methysergide, a drug which abolishes both the slow e.p.s.p. and the action of exogenous serotonin<sup>5,6</sup>, does not affect the action of substance P on guinea pig myenteric neurones. The results suggest that substance P is unlikely to be the neurotransmitter which mediates the slow e.p.s.p.

We used conventional methods, which are described in detail elsewhere, to record intracellular electrical activity and to evoke the slow e.p.s.p. in myenteric ganglion cells of guinea pig small intestine<sup>3</sup>. Substance P from three different sources (Beckman, Serva and Sigma) and methysergide (Sandoz) were applied to the neurones by adding the drugs to the superfusion solution.

We tested substance P 41 times on 35 ganglion cells from 15 guinea pigs. The compound produced a dose-dependent membrane depolarisation in 30 of the ganglion cells and had no effect on 5 of the cells (Figs 1, 2). In 22 neurones, the depolarisation was accompanied by an increase in membrane resistance, with a decrease in 8. The increase in input resistance did not seem to be related to membrane rectification, and probably reflects decreased membrane conductance for potassium, as suggested by Katayama and North<sup>4</sup>. The membrane depolarisation reached a plateau, and after 45–60 s in substance P, repolarisation, apparently reflecting tachyphylaxis, began. The effects of substance P were reversed when the preparations were washed with drug-free Krebs solution (Fig. 1).

Substance P had the same dose-dependent effects in the presence and absence of methysergide (Fig. 2). On all occasions, the membrane depolarisation produced by the three concentrations of substance P in the presence of methysergide was not significantly different ( $P > 0.10$ ) from the values obtained in its

**Fig. 1** Effects of methysergide on the slow e.p.s.p. and on the action of substance P in a myenteric neurone of guinea pig small intestine. Each neurone was impaled with the microelectrode and the following procedure carried out. (1) Constant current, hyperpolarising pulses were continuously injected into the neurone at 1-s intervals to monitor changes in the neurone's input resistance. (2) Three concentrations of substance P (10, 100 and 300 nmol l<sup>-1</sup>) were applied to the neurone in succession, but in variable order. Each concentration of substance P remained in contact with the neurone for 2 min and was then washed from the superfusion system for a period of 5 min with drug-free Krebs solution before addition of the next concentration of substance P. (3) The slow e.p.s.p. was evoked by electrical stimulation of one of the interganglionic fibre tracts that entered the ganglion. (4) Methysergide 20 μmol l<sup>-1</sup> was then added to the superfusion solution. (5) After 5 min in the presence of methysergide, electrical stimulation was again applied to the fibre tract. The same stimulus parameters were used and the stimulating electrode remained in the same position on the fibre tract throughout the experiment on each neurone. (6) The three concentrations of substance P were then applied in the same manner in the continuous presence of methysergide. (7) The methysergide was washed from the superfusion system and electrical stimulation was again applied to the fibre tract. (8) Current-voltage relationship and rectifying properties of the neuronal membrane were examined. The microelectrode was sometimes dislodged from the cell before completion of the above sequence and this is reflected in the numerical data of Fig. 2. We also sometimes repeated the entire sequence on the same cell. *a*<sub>1</sub>, Slow e.p.s.p. evoked by application of a short train of stimulus pulses (arrows) to one of the fibre tracts that entered the ganglion. Increased amplitude of the electrotonic potentials produced by current injection (increase in baseline width) reflected an increase in the input resistance of the neurone during the depolarising phase of the e.p.s.p. One spike with a long-lasting hyperpolarising after-potential occurred at the peak of the e.p.s.p. *b*<sub>1</sub>, Fibre tract stimulation did not evoke a slow e.p.s.p. in the presence of methysergide. *a*<sub>2</sub> (100 nmol l<sup>-1</sup>), *a*<sub>3</sub> (300 nmol l<sup>-1</sup>). Dose-dependent depolarising action of substance P. *b*<sub>2</sub> (100 nmol l<sup>-1</sup>), *b*<sub>3</sub> (300 nmol l<sup>-1</sup>). The presence of methysergide did not reduce the dose-dependent action of substance P. This neurone in each case was exposed to substance P for 2 min and then substance P washed from the superfusion system.

**Fig. 2** Dose-dependent effect of substance P on the electrical potential across the membrane of guinea pig myenteric neurones in the presence and absence of 20 μmol l<sup>-1</sup> methysergide. The maximal amount of depolarisation produced by each concentration of substance P is expressed as the per cent of the resting potential before application of the peptide. Results given are mean values, s.e.m.s, number of trials per concentration and the level of statistical significance. The arc sine transformation and Student's *t* statistics<sup>8</sup> were used to determine the level of significant difference between the means for each concentration of substance P in the presence and absence of methysergide. □, Substance P; ■, Substance P + methysergide.

absence. Similarly, the changes in input resistance produced by substance P were unaffected by methysergide. On the other hand, on the same cells, the presence of methysergide abolished the stimulus-evoked slow e.p.s.p. (Fig. 1), but this effect was reversed by washing the preparation with drug-free solution. Previous studies indicated that this blocking action of methysergide was due to a specific action at serotonin receptors and not a local anaesthetic action, because electrical stimulation still elicited spike discharge in the neurone when the slow e.p.s.p. was blocked in the presence of methysergide<sup>5,6</sup>.

Our observation that methysergide abolishes the slow e.p.s.p. without affecting the action of substance P makes it unlikely that substance P is the transmitter. Methysergide does block the action of serotonin and this, as well as several other lines of evidence, implicate serotonin as the neurotransmitter<sup>5</sup>. In the brain, the observation that substance P and serotonin occur within the same synaptic vesicles<sup>7</sup> suggests a functional relationship between the two substances; however, such a relationship has not yet been demonstrated.

## Serum triggers a sequence of rapid ionic conductance changes in quiescent neuroblastoma cells

SERUM is required for the growth of nearly all animal cells in culture, but the mechanisms by which serum interacts with cells are largely unknown<sup>1,2</sup>. Evidence exists, however, that the primary site of action of the serum constituents is at the plasma membrane. For example, the first detectable events following serum stimulation of resting fibroblasts involve alterations in membrane transport, such as a stimulation of the (Na<sup>+</sup> + K<sup>+</sup>)ATPase<sup>3,4</sup> and an increase in the uptake of various nutrients<sup>5</sup>. Most of this evidence has been obtained using tracer flux techniques, but the relatively poor time resolution of this method (of the order of minutes) has precluded detection of dynamic membrane changes that may occur within seconds of serum addition. We have applied intracellular electrophysiological techniques in a search for rapid ionic membrane events following serum stimulation of mouse neuroblastoma cells. These cells stop growing (become 'quiescent') after serum removal and begin to extend neurites, but on re-addition of serum the neurites retract and cell division resumes<sup>6,7</sup>. Here we report that the immediate consequence of adding fetal calf serum (FCS) to quiescent neuroblastoma cells is a triphasic

**Fig. 1** *a*, Intracellular recording from a N1E-115 cell during addition of FCS (Flow lot no. 2927028) showing the characteristic triphasic voltage response. Arrow indicates time at which the bathing solution was rapidly exchanged for serum-containing solution (final FCS concentration 30%). Membrane resistance was monitored as the voltage response to brief hyperpolarising current pulses (200 ms; 0.1–0.5 nA). Dashed line represents zero potential level. *b*, Oscilloscope recording of the initial phase, clearly showing the changes in membrane resistance. Membrane resistance during peak of phase I was decreased as much as eight-fold (corrected for voltage dependence). Temperature was  $36 \pm 1^\circ\text{C}$ .

membrane potential response, caused by a series of transient ionic permeability changes, the first of which is a rapid and transient increase in  $\text{Na}^+$  conductance. These conductance changes, which are distinctly different from those underlying electrical excitability, seem to be the first events following serum stimulation and may provide a clue to the mode of action of serum growth factors.

Cells of mouse neuroblastoma clone N1E-115 (ref. 8) were used as the model system because their relatively large cell size and their high specific membrane resistance make them most suitable for electrophysiological study<sup>9,10</sup>. The N1E-115 cells were grown at  $37^\circ\text{C}$  on circular glasses (diameter 1.5 cm; plating density  $2 \times 10^4$  cells per  $\text{cm}^2$ ) for 2 d in Dulbecco's modified Eagle's medium (DMEM) containing 10% FCS and 20 mM HEPES (pH 7.4), and were subsequently incubated in serum-free DMEM for at least 24 h. For experimental convenience dimethyl sulphoxide (DMSO, 2% v/v) was sometimes added to the growth medium to induce an enlargement of the average cell size<sup>11</sup>. DMSO treatment had no effect on the serum-dependent membrane properties.

Intracellular recordings were made with conventional electrophysiological techniques<sup>10</sup>, while the cells were bathed either in serum-free DMEM (0.5 ml;  $35\text{--}37^\circ\text{C}$ ) or in a salt solution with the equivalent ionic composition (130 mM NaCl; 5.5 mM KCl; 1.8 mM  $\text{CaCl}_2$ ; 0.8 mM  $\text{MgCl}_2$ ; 20 mM HEPES, pH 7.4). Heat-inactivated FCS was added by exchanging within a few seconds the serum-free solution for FCS-containing solution.

**Fig. 2** Effects of increased  $\text{Ca}^{2+}$  concentration on the serum-induced voltage response. After FCS addition in normal solution (*a*) the culture was washed and exposed to a 10 mM  $\text{Ca}^{2+}$  saline. The same cell was then re-penetrated and after adjustment of the resting potential to its original level, FCS (containing 10 mM  $\text{Ca}^{2+}$ ) was added again (*b*). Note the marked enhancement of phase II in a hyperpolarising direction, accompanied by a reduction in membrane resistance. Dashed lines represent zero potential level.

N1E-115 cells in serum-free medium maintained resting potentials between  $-30$  and  $-45$  mV and had membrane resistances varying from 10 to 40 M $\Omega$ . As illustrated in Fig. 1, addition of FCS (final concentration 30%) immediately elicited a characteristic triphasic voltage response. The initial phase (I) was a rapid depolarisation, reaching maximum values between  $-5$  and  $-15$  mV within a few seconds, accompanied by a substantial fall in membrane resistance. During the next 5–10 s the membrane repolarised to a potential value near the original resting level (phase II), while the membrane resistance only partially recovered. This hyperpolarising phase was followed by a new depolarising phase (III), accompanied by a gradual decrease in membrane resistance. Phase III reached a plateau value of about  $-25$  mV at 40–70 s following FCS stimulation. Finally, both membrane potential and resistance slowly increased again to new steady-state values which were consistently lower than the prestimulation values. This final recovery usually took 4–8 min, but was occasionally much slower (up to 20 min). Peak values of the serum response were dose dependent, showing saturation at a FCS concentration of about 30%. Addition of DMEM containing a high concentration of bovine serum albumin (BSA, final concentration 25 mg  $\text{ml}^{-1}$ , corresponding to the value in 50% serum) was without any electrical effect. After washing out the FCS-containing medium the serum response could be elicited again in the same cell. This procedure could be repeated several times before the response eventually became 'desensitised'.

**Fig. 3** Effects of growth-depleted and fresh serum (20%) on the same cell. Depleted FCS was obtained by a 3-day exposure of DMEM and 20% FCS to a confluent N1E-115 culture, with daily adjustment of the medium pH to 7.4. Dashed line represents zero potential level.

The ionic mechanisms underlying the sequential phases were evaluated by measuring the null or reversal potential of the distinct peaks as a function of changes in the external ionic concentrations. The null potential of phase I varied between  $-5$  and  $+10$  mV and was dependent on the external  $\text{Na}^+$  concentration. A threefold reduction of  $[\text{Na}^+]$  (choline substituted) resulted in a 20 mV shift of the null potential. A 10-fold reduction of external  $[\text{Ca}^{2+}]$ , however, did not significantly influence the properties of phase I. These results indicate that phase I is mainly caused by an increase in  $\text{Na}^+$  permeability. This phase is not affected by the  $\text{Na}^+$ -channel blocker tetrodotoxin ( $10^{-6}$  g  $\text{ml}^{-1}$ ), however, and corresponds to a peak of inward current in voltage-clamp conditions (not illustrated). Thus, it follows that the serum-activated  $\text{Na}^+$  conductance is clearly different from the voltage-dependent  $\text{Na}^+$  channel underlying the generation of the neuroblastoma action potential<sup>10</sup>.

Phase II reached maximum hyperpolarising values of up to  $-45$  mV. In view of the reduced resistance value this suggests an increase in permeability to  $\text{K}^+$ , which is the only ion with an equilibrium potential ( $E_K$ ) more negative than the resting potential ( $E_K = -75$  mV (ref. 10)). The activation of one component of the  $\text{K}^+$  permeability in neuroblastoma cells has been found to depend on  $\text{Ca}^{2+}$  influx<sup>12</sup>. Enhancing the driving force for  $\text{Ca}^{2+}$  influx by increasing external  $[\text{Ca}^{2+}]$  from 1.8 to 10 mM resulted in a striking shift of the peak value in a hyperpolarising direction towards  $E_K$ , accompanied by a further

decrease of the membrane resistance (Fig. 2). Maximum peak II values in high  $[Ca^{2+}]$  solution approached  $-60$  mV and were reduced by about 40 mV following a 10-fold increase in external  $[K^+]$ .

The dependence of phase II on both external  $Ca^{2+}$  and  $K^+$  strongly suggests that this phase reflects an increase in  $K^+$  permeability, accompanied or preceded by a net  $Ca^{2+}$  influx into the cytoplasm. The resulting increase in intracellular  $[Ca^{2+}]$  is then thought to underlie the  $Ca^{2+}$ -dependent membrane hyperpolarisation<sup>12</sup>.

The reversal potential of phase III was around  $-25$  mV and was sensitive to changes in external  $[Na^+]$  and  $[K^+]$ , whereas changes in external  $[Ca^{2+}]$  were without significant effect. Quantitative evaluation of the ionic selectivity during phase III is difficult, however, as the internal ionic concentrations are likely to change during this prolonged phase of ionic 'leakiness'. We can state, nevertheless, that both  $Na^+$  and  $K^+$  permeability are enhanced during phase III.

The present results are the first direct evidence that serum rapidly triggers dynamic membrane permeability changes to  $Na^+$ ,  $Ca^{2+}$  and  $K^+$  in a specific temporal sequence. In the only previously published electrophysiological study on growth stimulation, serum has been reported to depolarise the membrane of embryonic rat cells, but the underlying ionic mechanisms have not been elucidated<sup>13</sup>. Interestingly, the present data are reminiscent of the first detectable events occurring at egg fertilisation. Sperm-egg interaction triggers a transient 'fertilisation potential', brought about largely by a rapid increase in  $Na^+$  permeability<sup>14</sup>.

A major and intriguing question now is to what extent the rapid serum effects are involved in the triggering of subsequent biochemical events, in particular those which ultimately lead to the initiation of DNA synthesis and cell division. For example, the rapid  $Na^+$  conductance changes might lead to a stimulation of  $Na^+$ -coupled transport processes and to an increase in  $(Na^+ + K^+)ATPase$  activity<sup>15</sup>. Figure 3 shows that application of growth-depleted FCS, incapable of supporting growth, fails to induce a significant electrophysiological response. This result supports the view that the rapid ionic events are due to the growth-promoting factors in serum. Future investigations of early changes in membrane-linked events as well as characterisation of the serum factors involved should clarify the possible role that the phenomena described here have in growth control.

## Gramicidin A crystals contain two cation binding sites per channel

GRAMICIDIN A, a pentadecapeptide antibiotic from *Bacillus brevis*, dimerises to form transmembrane channels in biological and synthetic membranes<sup>1-4</sup>. These channels are permeable to alkali cations and protons, impermeable to anions and blocked by calcium ions<sup>5-8</sup>. The high transport rate ( $\sim 10^7$  ions  $s^{-1}$ ), moderate selectivity and simplicity of the gramicidin channel make it an attractive model for elucidating the mechanism of ion transport in biological membranes. Our previous X-ray crystallographic study showed that crystals of native gramicidin and of its complex with caesium ion contain cylindrical channels which are formed from helical dimers of gramicidin<sup>9</sup>. We also found that the binding of caesium leads to a large conformational change: the length of the channel decreases from 32 to 26 Å, whereas the diameter of the cylinder formed by the peptide main chain atoms increases from about 5 to 6.8 Å. We report here X-ray studies showing that the same conformational change is induced by the binding of the potassium ion. Furthermore, the isomorphism of the  $K^+$ -complex and  $Cs^+$ -complex crystals enabled us to calculate difference Fourier projections and define the location of the ion-binding sites.

Crystals of the  $K^+$ -complex of gramicidin were grown at room temperature over a 1-yr period from a solution of 21 mM KSCN and 21 mM gramicidin (commercial mixture of gramicidins A, B and C from ICN Life Sciences Group) in methanol. X-ray diffraction data to 2.5 Å resolution were collected as described previously<sup>9</sup>. The unit cell dimensions of the  $K^+$ -gramicidin crystal are virtually the same as those of  $Cs^+$ -gramicidin (Table 1). Many intensity changes due to the substitution of  $K^+$  for  $Cs^+$ , a difference of 36 electrons, are evident in the  $0kl$  precession photograph shown in Fig. 1. A three-dimensional difference Patterson map was calculated using  $(|F_{Cs}| - |F_K|)^2$  as coefficients. The Harker peaks showed that the space group is  $P2_12_12$ , resolving an earlier ambiguity<sup>9</sup>. The 12 highest peaks in the difference map at 5 Å resolution were interpreted in terms of Harker peaks and cross peaks arising from four cation-binding sites in the asymmetric unit. The positions of anions could not be determined because the thiocyanate counterion was the same in both crystals. The cation-binding sites were refined individually, then in pairs, and finally all together at 5 Å and at 3 Å resolution, using the three centrosymmetric projections by the method of Dickerson *et al.*<sup>10,11</sup>. When the occupancies and temperature factors of the four sites were constrained to be equal, the centric  $R$  factor<sup>12</sup> was 0.36 at 3.0 Å resolution, and the Kraut  $R$  factor<sup>13</sup> was 0.088. The centric  $R$  factor dropped to 0.34 when the individual occupancies and temperature factors were allowed to vary. Table 2 gives the coordinates of these sites. Phases of the

**Fig. 1**  $(0kl)$  Precession photographs of crystals of  $K^+$ -gramicidin (a) and  $Cs^+$ -gramicidin (b). The average difference in structure factor between these isomorphous crystals is 16%. A number of significant intensity changes are evident by visual comparison of the two patterns.

**Fig. 2** Centric  $y$ -axis projection Fourier map of  $K^+$ -gramicidin at 2.9 Å resolution.

centric reflections were then calculated by the single isomorphous replacement method. Projection difference Fourier maps showed no additional sites. There remains an ambiguity in the phase of each general reflection when only a single isomorphous heavy atom derivative is available. As the heavy atom array is nearly centrosymmetric, a three-dimensional Fourier map calculated from this single derivative is also nearly centric and hence not interpretable at the atomic level.

A projection Fourier map of the  $K^+$  complex is shown in Fig. 2. The asymmetric unit contains two cylindrical channels. Each channel consists of two polypeptide chains and contains two bound cations. The central density in each channel corresponds to the bound ions. The channels at  $z = 0$  and  $z = 0.5$  are not crystallographically equivalent but appear very similar in projection (Fig. 2). They give rise to a pseudo-cubic-centred and pseudo-tetragonal packing<sup>9</sup>, and so their structures must be nearly the same. The axes of the channels are coincident with crystallographic  $2_1$  axes, thus limiting the maximum length of a channel to 26 Å, half of the 52 Å unit cell length. The pair of ion sites at  $z = 0$  and  $z = 0.5$  are related by a translation of nearly 0.25 in  $y$ , supporting the notion that the crystallographically independent channels have very similar structures.

**Table 1** Unit cell parameters of crystals of  $K^+$ - and  $Cs^+$ -gramicidin

Ion	Space group	$a$	$b^*$	$c$
$K^+$	$P2_12_12$	32.11 Å	52.23	31.09
$Cs^+$	$P2_12_12$	32.07 Å	52.29	31.20

\* Channel axis.

Conductance and spectroscopic studies of analogues of gramicidin A indicate that the two strands in the dimeric channel are antiparallel<sup>14-16</sup>. Hence, the two cation-binding sites in a channel are probably equivalent. The two possible symmetric arrangements of these sites are depicted in Fig. 3, which shows that they are either 2.5 Å from the ends of the channel or, alternatively, 2.5 Å on each side of the centre of the channel. Our finding of two cation-binding sites per channel in the crystalline state agrees with  $^{86}Rb^+$  flux studies<sup>17</sup> showing the bi-directional fluxes in the gramicidin channel in bilayer membranes are not independent and that two sites are simultaneously occupied. Moreover, the stoichiometry of  $K^+$  binding to gramicidin in methylene chloride is one per polypeptide chain<sup>18</sup>, and so two sites per dimeric channel are expected. The dependence of the conductance on the cation concentration also shows that at least two cations can simultaneously interact with the gramicidin channel<sup>19,20</sup>.

The binding of  $K^+$ , like that of  $Cs^+$ , shortens the channel from 32 to 26 Å and widens its diameter from 5 to 6.8 Å. The diameter cited here refers to the approximate average distance between the centres of the peptide backbone atoms on either side of the channel. The space available for ion binding is about 3.0 Å smaller (the sum of the van der Waals radii of the atoms on either side of the channel). It is interesting that the conformational changes elicited by the binding of these ions are

**Table 2** Cation-binding sites in an asymmetric unit in crystals of  $K^+$ - and  $Cs^+$ -gramicidin

Site	$x$	$y^*$	$z$
1	8.1 Å	-1.1 Å	-0.2 Å
2	8.0	4.2	0.3
3	7.9	11.6	16.5
4	8.5	16.9	16.1

The unit cell contains a total of 16 cation-binding sites. Two of the four sites in an asymmetric unit are situated near ( $x = 0.25$ ;  $z = 0$ ) and separated by 5 Å along the channel axis  $y$ , and another two sites are located near ( $x = 0.25$ ;  $z = 0.5$ ) and separated by 5 Å in  $y$ . Each of these four sites gives rise to three additional ones by space group symmetry. In particular, each site is repeated by crystallographic symmetry at the same  $x$  and  $z$  coordinates and translated by  $y = 0.5$  (26 Å). Hence, each site is separated from its neighbours along the  $y$ -axis by 5 Å on one side and by 21 Å on the other side.

virtually identical although their ionic radii differ significantly (1.33 Å for  $K^+$ , 1.67 Å for  $Cs^+$ , ref. 21). We have also found that a new tetragonal form of a  $CsSCN$  complex of gramicidin is isomorphous with a thallos acetate complex.

Our results thus far are consistent with the existence of two major conformations for the gramicidin channel, an ion-free conformation observed in two crystal forms<sup>9</sup>, and an ion-bound conformation observed in the crystal complexes with  $Cs^+$ ,  $K^+$  and  $Tl^+$ . The ion-free conformation seems to be substantially independent of whether the solvent is methanol, ethanol or water. The helical Patterson peaks are the same for the methanol and ethanol crystals<sup>9</sup>. Furthermore, ethanol can be exchanged for 50% ethanol-50%  $H_2O$  with almost no change in the diffraction pattern. The large structural difference between forms with and without ions is likely to be due to a rearrangement in the hydrogen-bonding pattern, similar to that observed in valinomycin, an ion-carrier<sup>22,23</sup>. Some of the peptide  $C=O \cdots H-N$  hydrogen bonds are probably broken as the peptide carbonyl oxygens tilt inwards to coordinate the incoming cation. These interactions could not occur in the 5 Å diameter of the native channel because of steric hindrance. It seems likely that the gramicidin channel widens on binding

**Fig. 3** Schematic drawing showing the two possible symmetric arrangements of the cation-binding sites in a gramicidin channel. Adjacent sites are separated by 5 Å and by 21 Å in a 26 Å-long channel.

cations to permit peptide carbonyl-metal coordination, which compensates for some of the free energy lost in partially dehydrating the transported ion.

## Seminalplasmin—an antimicrobial protein from bovine seminal plasma which acts in *E. coli* by specific inhibition of rRNA synthesis

SEMINAL PLASMA—the fluid in which spermatozoa are ejaculated—has been known to inhibit reversibly both RNA and protein synthesis in sperm cells<sup>1-3</sup>. Here we report the isolation from seminal plasma, purification to homogeneity, and characterisation of a protein which we have called 'seminalplasmin', that specifically inhibits rRNA synthesis in *Escherichia coli* and is highly antimicrobial.

As transcription and translation in bovine spermatozoa are exclusively mitochondrial<sup>4,5</sup> and as there are close similarities between mitochondrial and prokaryotic transcription and translation, we used inhibition of the growth of *E. coli* to assay seminalplasmin during purification. Dialysed bovine seminal plasma was passed through a DEAE-Sephadex column and seminalplasmin was purified to homogeneity from the unadsorbed fraction by successive fractionation on a CM-Sephadex, a Sephadex G-75 and a [5'-(*p*-aminophenylphosphoryl)uridine-2'(3')-phosphate]-agarose (APU-agarose) affinity column (see Fig. 1). The use of the latter column removed traces of RNase SPL<sup>6</sup>. The DEAE-Sephadex column removed an inhibitor, 'antiseminalplasmin', which we have partially purified. Seminalplasmin obtained after the affinity chromatography was

**Table 1** Effect of seminalplasmin at various stages of purification, on the growth of *E. coli*

Stage of purification	Concentration of protein ( $\mu\text{g ml}^{-1}$ )	Inhibition of the growth of <i>E. coli</i> (%)
CM-Sephadex peak 4	40	100
	20	100
	10	40
	5	0
Sephadex G-75 fraction C	40	100
	20	100
	10	90
	5	50
Homogeneous seminalplasmin (after affinity chromatography)	40	100
	20	100
	10	90
	5	50

Aliquots of a logarithmically growing culture of *E. coli* W 160-37 ( $A_{760}$ , 0.01) were incubated with various concentrations of seminalplasmin-containing protein fraction. After 6 h, the  $A_{760}$  of the culture was measured. The absorbance of the culture to which no seminalplasmin was added,  $A_{760}$  of 0.5-0.6, was taken as 100 for the purpose of calculation of the percentage inhibition. For details of the fractions used for the growth-inhibition assay, see Fig. 1 and text. Affinity chromatography removed traces of RNase SPL contamination in Sephadex G-75 fraction C which was otherwise pure seminalplasmin. An  $A_{280}$  of 1 was taken to be equivalent to 1 mg of protein throughout this study. The composition of the growth medium was as follows ( $\text{g l}^{-1}$ ):  $\text{NH}_4\text{Cl}$  0.5;  $(\text{NH}_4)_2\text{SO}_4$  0.5;  $\text{KH}_2\text{PO}_4$  13.6;  $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$  0.02;  $(\text{NH}_4)_2\text{Fe}(\text{SO}_4)_2 \cdot 6\text{H}_2\text{O}$  0.0156; glucose 20; L-arginine hydrochloride 0.1. The above assay for growth inhibition would not detect the presence of a small number (<2% of the control) of viable organisms in the culture. Similar results were obtained with the other strains of *E. coli* tried.

homogeneous in both non-SDS and SDS polyacrylamide gel electrophoresis (PAGE)<sup>7-9</sup> (Fig. 1), in an analytical ultracentrifuge (sedimentation coefficient, 1.04S), and in an isoelectric focusing run on a column<sup>10</sup> (isoelectric point, 9.8); it was free of any detectable RNase, DNase or protease activity<sup>11</sup>.

The amino acid composition of seminalplasmin is, in mol per 100 mol of total amino acids (except Trp) was: Lys 12.30; Arg 9.60; His 4.15; Asx 11.26; Glx 4.92; Phe 3.95; Tyr 1.66; Pro 3.13; Cys 2.98; Thr 1.75; Ser 7.20; Gly 5.75; Ala 7.90; Val 0.63; Leu 14.20; Ile 1.80. The protein is rich in basic amino acids and contains no methionine.

The molecular weight of seminalplasmin was 17,000 by SDS-PAGE carried out as in ref. 8; 10,600 by SDS-PAGE carried out according to Laemmli<sup>9</sup>; 8,000 by ultracentrifugation, and 19,800 (minimum value) when calculated from the amino acid composition. The discrepancy between these values may be a reflection of certain uncommon structural features—such as an abnormally high axial ratio—in the protein.

The average yield of pure seminalplasmin was 18 mg per 100 ml of semen (average ejaculate, 4 ml); the total content of seminalplasmin in bovine semen is probably twice as much.

**Table 2** Effect of seminalplasmin on the growth of microorganisms

Petri dish no.	Microorganism	Description	Test substance Amount per disk (nmol)	Diameter of the zone of inhibition (mm)
1	<i>Candida albicans</i>	Seminalplasmin	5	15
		Streptomycin	17	0
		Chloramphenicol	53	0
2	<i>Salmonella typhimurium</i>	Seminalplasmin	5	15
		Streptomycin	17	8
		Chloramphenicol	53	15
3	<i>E. coli</i>	Seminalplasmin	5	15
		Streptomycin	17	8
		Chloramphenicol	53	15

Exponentially growing broth cultures were transferred to medium 199-Earle's salts plates (one for each organism) using a heavy inoculum which, on normal growth, would give a 'mat'. Disks impregnated with the stated amount of substance were placed on the surface of the culture just after the inoculation, and the diameter of the clear zone measured after 20 h at 37 °C. The strains used were isolated at the Institute of Preventive medicine, Hyderabad, where the testing was done. The two bacterial strains were partially resistant to streptomycin.

**Fig. 1** Purification of seminalplasmin. Seminal plasma (200 ml) obtained from bovine semen following removal of spermatozoa by centrifugation was dialysed against Tris-HCl buffer (0.006 M, pH 7.4) and the dialysed plasma passed through a DEAE-Sephadex column (5 × 60 cm) equilibrated with the above buffer. The fraction that came out unadsorbed from the DEAE-Sephadex column was chromatographed on a CM-Sephadex C-50 column (2 × 45 cm) equilibrated with the Tris-HCl buffer and eluted with a linear gradient of 0–0.8 M NaCl in the same buffer. The peaks were pooled as marked, dialysed against water and lyophilised to give the crude seminalplasmin. In some runs, peaks 3 and 4 were not separated. Peaks 1 and 2 had no detectable seminalplasmin activity, while peak 3 had some activity which was possibly due to cross contamination with peak 4. The crude seminalplasmin (peak 4 of a, 100 mg; where peaks 3 and 4 were not separated, the trailing part of the combined peak was used) was then chromatographed on Sephadex G-75 (2.6 × 170 cm) equilibrated with Tris-HCl buffer (pH 7.4) and eluted with the same buffer. The pooled fractions A, B and C were dialysed separately against water and lyophilised. Fraction C was dissolved in 0.02 M acetate buffer (pH 5) and chromatographed on a APU-agarose affinity column (0.8 × 6 cm) equilibrated with the acetate buffer. The column was washed with the same buffer; the unadsorbed fraction consisted of pure seminalplasmin (the adsorbed fraction contained RNase SPL). a and b, typical CM-Sephadex and Sephadex G-75 column runs, respectively. c, Polyacrylamide gel electrophoresis runs of various fractions. (1)–(5), Non-SDS PAGE<sup>7</sup>; (6) SDS-PAGE<sup>8</sup>. (1) CM-Sephadex peak 4; (2) Sephadex fraction A; (3) Sephadex fraction B; (4) Sephadex fraction C; (5) and (6) the part of Sephadex fraction C that was unadsorbed on the APU-agarose affinity column (pure seminalplasmin). (1) Expt 1; (2) to (5) expt 2; (6) expt 3. Each gel was loaded with 100 µg of protein. The gels were stained with Coomassie blue (0.1%) in ethanol:water:acetic acid (45:45:10 v/v). Several protein fractions which could be separated on non-SDS PAGE in (1) moved together on SDS-PAGE done as in (6).

Seminalplasmin potently inhibited the growth of Gram-positive and Gram-negative bacteria and yeasts. In liquid cultures grown in a synthetic medium, starting from an inoculum of  $10^6$ – $10^7$  colony forming units (CFU)  $\text{ml}^{-1}$  for bacteria and  $10^5$ – $10^6$  CFU  $\text{ml}^{-1}$  for yeasts, seminalplasmin completely inhibited the growth of *Streptococcus faecalis*, *E. coli* and *Cryptococcus neoformans* at 50–100 µg (2.5–5.0 nmol), 25–50 µg (1.25–2.50 nmol), and 12.5–25 µg (0.63–1.26 nmol) per ml, respectively (see Table 1). Comparable inhibition of growth of organisms considered sensitive to established antimicrobial agents was (nmol  $\text{ml}^{-1}$ ): penicillin and streptomycin, 1.7–8.5; chloramphenicol, 9–27; tetracyclines, 2.2–11; erythromycin, 1.4–2.8; bacitracin, 4.5–9; polymyxin, 0.9–2.2. In disk agar assays, seminalplasmin was active against *Salmonella typhimurium* and *Candida albicans*; it was also active against *Bacillus subtilis* and *Staphylococci* in another type of assay. Seminalplasmin, however, showed no activity against *Pseudomonas* and *Proteus* spp. Results of some typical antimicrobial assays of crude seminalplasmin fractions and the pure protein are shown in Tables 1 and 2.

Seminalplasmin is bacteriocidal and not bacteriostatic. When a culture of *E. coli* W 160-37 containing  $\sim 10^7$  cells  $\text{ml}^{-1}$  was incubated with seminalplasmin ( $\geq 40$  µg  $\text{ml}^{-1}$ ) for 7 h at 37 °C (when the control contained  $2.3 \times 10^8$  cells  $\text{ml}^{-1}$ ), and then 50 µl of the culture plated on nutrient agar, complete inhibition of growth was normally obtained. Occasional colonies of apparently seminalplasmin-resistant cells were seen.

The concentration of seminalplasmin needed to inhibit the growth of *E. coli*, as assayed in Table 1, depended on the number of cells present in the culture; whereas for  $10^7$  cells  $\text{ml}^{-1}$ , the concentration required was 10–20 µg  $\text{ml}^{-1}$ , for  $5 \times 10^7$  cells  $\text{ml}^{-1}$ , 40–50 µg  $\text{ml}^{-1}$ , for  $10^8$  cells  $\text{ml}^{-1}$ , 60–70 µg  $\text{ml}^{-1}$ , and for  $2 \times 10^8$  cells  $\text{ml}^{-1}$ , 100–110 µg  $\text{ml}^{-1}$  of seminalplasmin was required.

Seminalplasmin is relatively heat stable; when *E. coli* cells ( $10^7$   $\text{ml}^{-1}$ ) were grown in the presence of seminalplasmin (40 µg  $\text{ml}^{-1}$ ) heated at 90 °C for 10 min, over 95% inhibition of growth was obtained at 6 h, compared with 100% inhibition with untreated seminalplasmin. Lyophilised, pure seminalplasmin is stable for at least 2 yr at 4 °C; in aqueous solution it is stable for at least 6 months when stored frozen.

A 52% inhibition of the synthesis<sup>3,4</sup> of RNA in bovine spermatozoa, measured over a period of 2.5 h, was seen with seminalplasmin (1 mg  $\text{ml}^{-1}$ ) preincubated with the cells for

30 min, suggesting that at least part of the total transcription-inhibiting activity of bovine seminal plasma is due to seminalplasmin. Seminalplasmin had no effect on respiration in spermatozoa studied over a period of 2 h using fructose (the semen sugar) as the oxidisable substrate.

Seminalplasmin (100 µg  $\text{ml}^{-1}$ ) had no effect on the rates of synthesis of DNA and protein in *E. coli* W160-37—at least up to 15 min—in pulse-labelling experiments (Fig. 2a, c). The rate of incorporation of <sup>3</sup>H-uridine into RNA, however, progressively fell to about 50% of the control at 8 min (Fig. 2b); beyond this

**Fig. 2** Effect of seminalplasmin on the rate of synthesis of DNA (a), RNA (b) and protein (c). a, A sample of 6 ml of a logarithmically growing culture of *E. coli* ( $A_{760}$ , 0.3) was incubated with seminalplasmin (100 µg  $\text{ml}^{-1}$ ). At each time point, a 0.5-ml aliquot of the culture was pulse-labelled for 20 s with 13.3 µCi (0.41 µg) of <sup>3</sup>H-thymidine added in 0.2 ml of the growth medium. The reaction was stopped with 5 ml of cold 5% trichloroacetic acid (TCA), and 0.1 ml of 0.5% bovine serum albumin was added. The precipitate was filtered on a Whatman 3 MM filter, washed three times with 10 ml of cold 5% TCA, dried and counted. b, The experimental protocol was as in a but pulse-labelling was with <sup>3</sup>H-uridine (13.3 µCi, 0.32 µg). c, Pulse labelling was as in a but with 1 µCi (0.65 µg) of <sup>14</sup>C-leucine. The TCA precipitate was heated with 5% TCA at 95 °C for 30 min and then filtered, washed and counted. Counting efficiency was 40% for <sup>3</sup>H and 80% for <sup>14</sup>C.

time no further decrease in rate of RNA synthesis was observed, suggesting that seminalplasmin may be specifically inhibiting the synthesis of a certain type(s) of RNA. In pulse-labelling experiments such as those shown in Fig. 2b, the label is known to be roughly equally distributed between mRNA and rRNA. Since protein synthesis was not affected for at least 20 min, it seemed unlikely that seminalplasmin was inhibiting the synthesis of mRNA. In *E. coli* cells ( $A_{760}$ , 0.2) preincubated with seminalplasmin ( $170 \mu\text{g ml}^{-1}$ ) for 15 min, the induction of  $\beta$ -galactosidase with isopropylthiogalactoside was also normal. We showed that seminalplasmin specifically inhibits the synthesis of rRNA in *E. coli*, by analysing on PAGE the RNA labelled in 20 min in the presence of seminalplasmin ( $100 \mu\text{g ml}^{-1}$ ) in a growing culture of *E. coli* which had been preincubated with the protein for 15 min (Fig. 3). Seminalplasmin inhibited the labelling of rRNA by 85%; tRNA synthesis was inhibited by  $\sim 10\%$ , probably through inhibition of the transcription of genes for tRNA that are a part of the rRNA cistrons in *E. coli*<sup>12</sup>. In line with these observations, addition of seminalplasmin ( $100 \mu\text{g ml}^{-1}$ ) to *E. coli* cultured in the presence of  $^3\text{H}$ -uridine almost completely stopped the increase in the label appearing in total RNA after 12 min in cells growing in the absence of chloramphenicol (Fig. 4a), and completely stopped it in chloramphenicol-treated non-growing cells (Fig. 4b) in which the RNA that is labelled is almost entirely transcribed from rRNA cistrons. In cells treated with chloramphenicol and seminalplasmin, the RNA labelled in the first 12 min (the time presumably required for building up of the intracellular concentration of seminalplasmin necessary for its full inhibitory effect) was subsequently degraded (Fig. 4b); this degradation—also observed in the presence of rifampicin instead of seminalplasmin<sup>13</sup>—may be related to the instability of rRNA synthesised in the presence of chloramphenicol, hence not protected by ribosomal proteins.

**Fig. 3** Fractionation by polyacrylamide gel electrophoresis of *E. coli* RNA synthesised in the presence or in the absence of seminalplasmin. Aliquots of 5 ml of a logarithmically growing culture of *E. coli* ( $A_{760}$ , 0.30) were incubated with or without seminalplasmin ( $200 \mu\text{g ml}^{-1}$ ). At 10 min,  $^3\text{H}$ -uridine ( $45 \mu\text{Ci}$ ,  $10.1 \mu\text{g}$ ) was added to both the aliquots. At 35 min,  $50 \mu\text{l}$  of 2% sodium azide and 1 mg of  $^{12}\text{C}$ -uridine were added and the solution was immediately kept in an ice-salt bath. Unlabelled *E. coli* RNA (2 mg) was then added and RNA isolated from both the samples by extraction with aqueous phenol at pH 5.2. RNA solutions were dialysed and fractionated on a 2.5% polyacrylamide gel, and the gels cut and counted. Arrows indicate the positions of the carrier (non-radioactive) 23S, 16S and 5S-4S RNA fractions visualised by staining with methylene blue (0.01% in 0.01 M acetate buffer, pH 4.7).  $\circ$ , Without seminalplasmin;  $\bullet$ , with seminalplasmin.

In *E. coli* in the presence of a high concentration of seminalplasmin ( $200 \mu\text{g ml}^{-1}$ ), the rate of protein synthesis also started to decrease after 10 min; the fall was linear, reaching 50% of control at 26 min. In the presence of  $100 \mu\text{g}$  of seminalplasmin per ml, the rate of protein synthesis started to fall (linearly) only after 15–20 min, reaching 50% of the control after 40 min. An eventual decline in the rate of protein synthesis is to be expected as a consequence of cessation of rRNA synthesis.

**Fig. 4** a, Effect of seminalplasmin on RNA synthesis in *E. coli*. Aliquots of 11 ml of a logarithmically growing culture of *E. coli* ( $A_{760}$ , 0.3) were incubated for various periods at  $37^\circ\text{C}$  with (or without) seminalplasmin ( $100 \mu\text{g ml}^{-1}$ ), in the presence of  $^3\text{H}$ -uridine ( $3.9 \mu\text{Ci ml}^{-1}$ ,  $7.88 \mu\text{g ml}^{-1}$ ). At each time point, a 0.5-ml aliquot from each of the incubated cultures was precipitated with 5 ml of ice-cold 5% TCA containing an excess of  $^{12}\text{C}$ -uridine; the radioactivity ( $x$ ) of the precipitate was taken as a measure of labelling of the total nucleic acid. Another 0.5-ml aliquot from the culture was treated with an equal volume of 1 M KOH for 18 h at  $37^\circ\text{C}$ , neutralised and then made 5% with respect to TCA; the radioactivity ( $y$ ) in the precipitate gave the extent of labelling of DNA.  $x - y$  gave the radioactivity in RNA. b, Effect of seminalplasmin on RNA synthesis in a chloramphenicol-inhibited culture of *E. coli*. Aliquots of 11 ml of a logarithmically growing culture of *E. coli* ( $A_{760}$ , 0.26) were incubated at  $37^\circ\text{C}$  with (or without) seminalplasmin ( $212 \mu\text{g ml}^{-1}$ ), in the presence of chloramphenicol ( $149 \mu\text{g ml}^{-1}$ ) and  $^3\text{H}$ -uridine ( $1.86 \mu\text{Ci ml}^{-1}$ ,  $7.48 \mu\text{g ml}^{-1}$ ). Aliquots were taken from each culture at various times and the radioactivity in RNA and DNA determined as in (a). SPN, seminalplasmin; CLP, chloramphenicol.

The antimicrobial and *in vivo* rRNA-transcription inhibiting activities of seminalplasmin were completely abolished by pronase, trypsin, chymotrypsin or papain.

Figure 5 shows the effects of adding pronase ( $30 \mu\text{g ml}^{-1}$ ) to cultures of *E. coli* ( $A_{760}$  0.01) exposed to seminalplasmin ( $50 \mu\text{g ml}^{-1}$ ) for various intervals between 0 and 60 min. Addition of pronase at 0 min showed no inhibition of growth. Increased inhibition of growth was obtained as the time of exposure to seminalplasmin in the absence of pronase increased. A 30-min exposure to seminalplasmin ( $50 \mu\text{g ml}^{-1}$ ) seemed to be sufficient to allow the *E. coli* cells at  $\sim 10^7$  cells  $\text{ml}^{-1}$  to take up enough seminalplasmin to inhibit the growth completely. The experiments described in Figs 2 and 4 suggest that, at a higher concentration ( $100 \mu\text{g ml}^{-1}$ ), enough seminalplasmin enters the cells ( $\sim 3 \times 10^8 \text{ ml}^{-1}$ ) in 8–12 min to exert its maximal inhibitory effect on rRNA synthesis.

**Fig. 5** Effect of pronase on the growth of *E. coli* preincubated with seminalplasmin for various periods. To a set of tubes (one for each time point) containing the growth medium (5 ml) and seminalplasmin ( $50 \mu\text{g ml}^{-1}$ ), was added 1 ml of a logarithmically growing culture of *E. coli* ( $A_{760}$ , 0.06). The tubes were incubated at  $37^\circ\text{C}$  and, at each time point, pronase ( $30 \mu\text{g ml}^{-1}$ ) was added to one tube. After 6 h,  $A_{760}$  of all the cultures was measured. For calculation of the percentage inhibition of growth in the seminalplasmin and pronase-treated cultures, the growth ( $A_{760}$ , 0.5–0.6) obtained in a control culture to which no seminalplasmin but pronase was added, was taken as 100. Pronase, at the concentrations used, had no effect on the growth of *E. coli*; at higher concentrations ( $100 \mu\text{g ml}^{-1}$ ) it stimulated growth.

Seminalplasmin is apparently the fourth antimicrobial protein to be isolated from mammalian sources—the others being lysozyme,  $\beta$ -lysin, and a recently described protein from polymorphonuclear leukocytes<sup>14</sup>. After colicin E<sub>3</sub>, it appears to be the first protein for which there is strong evidence that it enters an intact bacterial cell. As seminalplasmin acts on a variety of microorganisms, it is unlikely that its entry into the cell—unlike that of colicin E<sub>3</sub>—is receptor-mediated. Seminalplasmin is also the first inhibitor shown to specifically inhibit the transcription of rRNA in a whole cell.

We first considered the possibility that seminalplasmin may have a role in fertilisation. In a year-long experiment we looked for a correlation between the net antibacterial activity (a function of the ratio of seminalplasmin to antiseminalplasmin, and the amount of each, in seminal plasma) of over 1,000 samples of bovine seminalplasma derived from 126 animals belonging to eight different breeds of two different bovine species (buffalo-bull and cow-bull), and the fertility of semen samples from which the seminal plasma was obtained (P.M.B. *et al.*, unpublished). The fertility was determined by artificial insemination of nearly 2,200 cows and buffaloes. To allow for seasonal variations, the samples were collected over the entire calendar year. Computer analysis of the data has shown no simple correlation between the net antibacterial activity of seminal plasma and the fertilising ability of the semen sample from which the particular batch of seminal plasma was derived.

It is tempting to speculate that the function of seminalplasmin is to act as an antimicrobial agent. It could provide protection either to the male or to the female through deposition of seminal plasma in the reproductive tract during sexual intercourse, or to both. If the natural function of seminalplasmin were to provide protection to the female, one might expect to find a higher incidence of microbial infection of the female genital tract in women who are celibate or have sexual intercourse only rarely, than in women who have frequent sexual intercourse. We are investigating this possibility.

We thank Mrs J. Kusuma Rao and Dr P. T. Iype for carrying out preliminary work; the Director of the Animal Husbandry Department, government of Andhra Pradesh, Hyderabad and IDL Chemicals, Hyderabad, for the supply of semen; Dr T. Subbaiah (Alembic Chemical Works, Baroda), Drs O. P. Srivastava and Nityanand (Central Drug Research Institute, Lucknow), Drs Jagannathan and K. Rajyalakshmi (Institute of Preventive medicine, Hyderabad) and Mrs N. Shyamala Rao for assistance with antimicrobial assays; the Director, International Crop Research Institute for Semi-Arid Tropics, Hyderabad, for amino acid analysis; and the Council of Scientific and Industrial Research, New Delhi, for the award of a research fellowship to E.S.P.R. Samples of seminalplasmin can be obtained from the Officer-in-Charge, CSIR Centre for Biochemicals, Vallabhai Patel Chest Institute, University of Delhi, Delhi 110 007, India.

## Seminalplasmin is a potent inhibitor of *E. coli* RNA polymerase *in vitro*

SEMINALPLASMIN, a protein isolated from bovine seminal plasma, specifically and almost completely inhibits synthesis of rRNA in whole *Escherichia coli* cells at extracellular concentrations lower than those needed for bacteriocidal action of many established antibacterial agents<sup>1</sup>. We show here that seminalplasmin also strongly inhibits the transcription of various natural and synthetic templates by *E. coli* RNA polymerase *in vitro*, and that it does so by binding strongly to the polymerase. Seminalplasmin is, to our knowledge, the first protein isolated from an eukaryote to inhibit RNA polymerase. There is, however, a protein synthesised in *E. coli* following a phage infection and coded by the phage genome, which appears to inhibit *E. coli* RNA polymerase<sup>2</sup>.

Pure seminalplasmin was prepared as described in the accompanying paper<sup>1</sup>. Figure 1 shows the effect of seminalplasmin on the transcription of various templates by *E. coli* RNA polymerase (holoenzyme), following a 12–30-min incubation of seminalplasmin with the polymerase alone (Fig. 1A–H) or with the template (Fig. 1G, H). With a polymerase concentration of 25  $\mu\text{g ml}^{-1}$  (in some cases, 50  $\mu\text{g ml}^{-1}$ ), the concentration of seminalplasmin required, in  $\mu\text{g ml}^{-1}$ , for 50% inhibition of the transcription of the various templates, following incubation of seminalplasmin with the polymerase for 30 min (15 min for poly(dI-dC)), was: poly(dA) 50; poly(dT) 50; poly(dA-dT) 50; poly(dG-dC) 100; poly(dI-dC) 100; poly(dA)-poly(dT) 30; T7 DNA 25; and calf thymus (CT) DNA 25. With all the templates except poly(dA-dT), poly(dG-dC) and poly(dI-dC), over 90% inhibition of transcription was obtained with seminalplasmin at 100  $\mu\text{g per ml}$  (5 nmol per ml, assuming a MW of 19,800; see ref. 1). For poly(dA-dT), poly(dG-dC) and poly(dI-dC), maximum inhibition obtained was 50–60% at a seminalplasmin concentration of 100  $\mu\text{g ml}^{-1}$ . Heating seminalplasmin for 10 min at 80 °C destroyed 90% of its transcription-inhibiting activity (Fig. 2).

The following four observations show that seminalplasmin did not possess any RNase, DNase or nonspecific protease activity that could account for its transcription inhibiting activity. (1) Seminalplasmin (130–140  $\mu\text{g ml}^{-1}$ ) did not release any acid-soluble radioactivity from—or change the polyacrylamide gel electrophoresis (PAGE) pattern of—<sup>14</sup>C-poly(rU) (37  $\mu\text{g}$  (80,360 c.p.m.) per ml) or <sup>3</sup>H-labelled total denatured *E. coli* RNA (500  $\mu\text{g}$  (360,000 c.p.m.) per ml) in 60 min at 37 °C, in conditions in which RNase A or RNase SPL (ref. 1) (8–12  $\mu\text{g ml}^{-1}$ ) converted 90–100% of the above substrates to acid-soluble material in 5–10 min. (2) Seminalplasmin (100  $\mu\text{g ml}^{-1}$ ) released no measurable acid-soluble radioactivity from <sup>3</sup>H-poly(dT) (14.8 nmol of TMP residues (1.18  $\times 10^6$  c.p.m.) per ml) on incubation for 30 min at 37 °C in the transcription buffer described in Fig. 1. (3) Seminalplasmin (50–480  $\mu\text{g ml}^{-1}$ ) did not affect the enzyme activity of  $\beta$ -galactosidase (5.5  $\mu\text{g ml}^{-1}$ ; homogeneous on PAGE) or polynucleotide phosphorylase (50  $\mu\text{g ml}^{-1}$ ), or did not release any 280 nm-absorbing or Folin reagent-positive acid-soluble material from casein (5 mg ml<sup>-1</sup>) in 20 min at 37 °C. (4) Addition of an excess (200  $\mu\text{g ml}^{-1}$ ) of bovine serum albumin to the transcription buffer (Fig. 1), did not affect the inhibition by seminalplasmin (100  $\mu\text{g ml}^{-1}$ ), of the transcription of poly(dT) by RNA polymerase (25  $\mu\text{g ml}^{-1}$ ).

The following two observations strongly suggest that seminalplasmin inhibits the transcription of various templates by binding to the RNA polymerase. (1) Increase in the concentration of RNA polymerase relieved the inhibitory effect of seminalplasmin on transcription (Fig. 3B). An increase in the concentration of the template had no such effect (Fig. 3C). (2) Incubation of seminalplasmin with the polymerase for 20–

**Fig. 1** Effect of seminalplasmin incubated with *E. coli* RNA polymerase, on the transcription of various templates. The reaction mixture contained, in 0.1 ml of Tris-HCl buffer (pH 7.8; for composition, see ref. 3): 0.15 mM of each of the substrates, UTP, GTP, CTP, ATP, and/or ITP, as required (with one of these substrates labelled with  $^{14}\text{C}$  or  $^{32}\text{P}$ ); *E. coli* RNA polymerase (holoenzyme, 5  $\mu\text{g}$  or 2.5  $\mu\text{g}$ ); template DNA; and seminalplasmin at the stated concentration. The templates used (in 0.1 ml of the incubation medium) were: T7 DNA (A), 0.244 pmol; CT DNA (B), 2.94  $\mu\text{g}$ ; poly(dA-dT) (C), 0.074  $A_{260}$  units; poly(dA-dT) (D), 0.1  $A_{260}$  units; poly(dG-dC) (E), 0.1  $A_{260}$  units; poly(dA) (F), 0.2  $A_{260}$  units; poly(dT) (G), 0.5  $A_{260}$  units; poly(dI-dC) (H), 0.05  $A_{260}$  units. In A to E, the polymerase and seminalplasmin were incubated for 30 min, DNA was added, the mixture was incubated for a further 5 min, and the reaction was started by the addition of the substrate mix. In F, the polymerase was incubated for 20 min without (a) or with (b) seminalplasmin (10  $\mu\text{g}$  in 0.1 ml). In G, either the polymerase and seminalplasmin (10  $\mu\text{g}$  in 0.1 ml) were incubated for 12 min (a), or the polymerase, seminalplasmin (10  $\mu\text{g}$  in 0.1 ml) and poly(dT) were incubated for 10 (b), 20 (c) or 30 (d) min; e, f, g and h are controls for a, b, c and d, respectively, in which the polymerase (or the polymerase and the template) was incubated without seminalplasmin. In H, the polymerase and seminalplasmin (10  $\mu\text{g}$  in 0.1 ml) were incubated for 20 min in a; the polymerase and seminalplasmin (10  $\mu\text{g}$  in 0.1 ml) and poly(dI-dC) were incubated for 15 min in b; and the polymerase alone was incubated for 20 min in c which served as the control for a and b. The time of reaction (6 min in A; 10 min in B-E; and the time given on the x-axis in F-H) was counted from the time of the addition of the substrate mix. The substrate mix contained all the four nucleoside triphosphates in the case of A and B; ATP and UTP in C and D; CTP and GTP in E; UTP in F; ATP in G; and ITP and CTP in H. The labelled precursors used were:  $^{14}\text{C}$ -UTP (2,808 c.p.m.  $\text{nmol}^{-1}$ ) in A, B, C (graph a) and F;  $^{14}\text{C}$ -ATP (2,776 c.p.m.  $\text{nmol}^{-1}$ ) in C (graph b), D and

G; [ $\alpha$ - $^{32}\text{P}$ ]CTP (24,000 c.p.m.  $\text{nmol}^{-1}$ ) in E and H. The concentration of the polymerase was 2.5  $\mu\text{g}$  in 0.1 ml in A-D; and 5  $\mu\text{g}$  in 0.1 ml in E-H. All incubations were carried out at 37  $^{\circ}\text{C}$ . A 20- $\mu\text{l}$  aliquot was withdrawn from the reaction mixture, spotted over a streak of glacial acetic acid on a  $10 \times 2$  cm strip of Whatman no. 3 filter paper, and chromatographed for 45 min in ethanol: ammonium acetate (1 M) (1:1) solvent. A 1-cm strip was cut along the original spot and the radioactivity in it measured; this radioactivity was taken as the measure of RNA synthesis<sup>4</sup>. An appropriate control, without seminalplasmin, was run in every case; the radioactivity (in c.p.m.) contained in RNA (20  $\mu\text{l}$  of the incubation mixture) in the control samples was: A 1,500; B 1,256; C(a) 1,468; C(b) 243; D 2,556; E 927. The same batch of RNA polymerase was used in all experiments described here. Its specific activity was 16,000 units per mg assayed with T7 DNA as the template, and it was 95% pure as judged by SDS-polyacrylamide gel electrophoresis; it contained 1 equivalent of the  $\sigma$  subunit. An  $A_{260}$  of 1 was taken to be equivalent to 1 mg of seminalplasmin.

30 min before the start of transcription was necessary for optimal inhibition of transcription (Fig. 1). Very much lower inhibition was obtained when seminalplasmin was added at the same time at which the transcription was started (Table 1). The inhibition was virtually abolished if seminalplasmin was added after (Fig. 3D)—or incubated with the template before (Fig. 3A)—the transcription was started.

That seminalplasmin indeed is bound tightly to RNA polymerase was shown by the following experiment. A mixture of the two proteins incubated for 30 min at 37  $^{\circ}\text{C}$  (as in Fig. 1) was chromatographed on a column of Sephadex G-75, on which column RNA polymerase and seminalplasmin, when chromatographed separately, were widely separated. RNA polymerase incubated with seminalplasmin (RP-S) was eluted in the

exclusion volume, like RNA polymerase incubated in the absence of seminalplasmin (RP) (Fig. 4). SDS-PAGE runs of the RP-S fractions showed that they contained seminalplasmin (Fig. 5). The subunit pattern, on SDS-PAGE, of RNA polymerase was not altered on binding seminalplasmin, showing that seminalplasmin did not exhibit any specific proteolytic activity towards the polymerase, or remove from it any of its subunits such as the  $\sigma$  factor (Fig. 5). In accord with these observations, incubation of seminalplasmin (50  $\mu\text{g ml}^{-1}$ ) for 1 h with an excess of RNA polymerase (200  $\mu\text{g ml}^{-1}$ , a concentration high enough to overcome the inhibition of transcription by seminalplasmin see Fig. 2B), did not lead to any loss in the transcribing ability of the polymerase.

As expected, the transcribing ability of RP-S, assayed on

**Table 1** Effect of seminalplasmin on transcription of various templates by *E. coli* RNA polymerase

Template		Substrate	(c.p.m. $\text{nmol}^{-1}$ )	% Inhibition of transcription by seminalplasmin at:

The effects of seminalplasmin on transcription were studied as in Fig. 1 in a total reaction volume of 0.1 ml, with the exception that seminalplasmin was added at the same time as the template, and the mixture preincubated only for 5 min before the reaction was started by the addition of substrate. The transcription was continued for 10 min [9 min for T7 DNA and poly(dT)] after the addition of the substrate mix, and 20- $\mu\text{l}$  aliquots were counted for estimation of radioactivity in RNA, as in Fig. 1. The final concentration of RNA polymerase in the incubation mixture was 50  $\mu\text{g ml}^{-1}$ .

**Fig. 2** Effect of heat on the transcription-inhibiting activity of seminal-plasmin. Seminalplasmin (8  $\mu$ g), in 75  $\mu$ l of Tris-HCl buffer (Fig. 1), was heated for 10 min at the stated temperature and chilled in ice. RNA polymerase (2.5  $\mu$ g in 5  $\mu$ l of buffer) was added and the mixture incubated for 30 min. T7 DNA (0.244 pmol; 10  $\mu$ l) was added, the mixture further incubated for 5 min, and the transcription started by the addition of the substrate mix (10  $\mu$ l) and carried out for 9 min, as in Fig. 1.  $^{14}$ C-UTP was used as the labelled substrate and the inhibition of transcription measured as described in Fig. 1.

poly(dA-dT) (Fig. 4) and poly(dA), was much lower than that of RP. Seminalplasmin apparently binds to *E. coli* RNA polymerase with high affinity: the transcription-inhibitory activity of the RNA polymerase-seminalplasmin complex formed after a 20-min incubation as in Fig. 1, was not affected on incubation of the complex for 20 min in the presence of 1 M NaCl.

**Fig. 3** A, Effect of incubation of the template with seminal plasmin on transcription. Poly(dT) (0.05  $A_{260}$  units) was incubated without (a) or with (b) 10  $\mu$ g seminal plasmin for 20 min, RNA polymerase (5  $\mu$ g) was then added, the mixture was further incubated for 5 min, and the reaction was started by the addition of  $^{14}$ C-ATP; 20- $\mu$ l aliquots were taken out at various times for measurement of radioactivity in RNA. The other details were as in Fig. 1. B, Effect of increasing the concentration of RNA polymerase on the inhibition of transcription of poly(dT) by seminal plasmin. RNA polymerase was incubated without (a) or with (b) seminal plasmin (5  $\mu$ g) for 12 min, poly(dT) (0.025  $A_{260}$  units) was then added, the mixture was further incubated for 5 min, and the reaction was started by the addition of  $^{14}$ C-ATP and carried out for 9 min. The other details were as in Fig. 1. C, Effect of increasing the concentration of the template on the inhibition of transcription of poly(dA-dT) by seminal plasmin. RNA polymerase (2.5  $\mu$ g) was incubated without (a) or with (b) seminal plasmin (5  $\mu$ g) for 30 min, the stated amount of poly(dA-dT) was then added, the mixture was incubated for a further 5 min, and the reaction was started by the addition of UTP and  $^{14}$ C-ATP and carried out for 6 min. Other details were as in Fig. 1. D, Effect of addition of seminal plasmin on the transcription of T7 DNA. The transcription was started as in Fig. 1 but without incubation with seminal plasmin; the reaction mixture contained 2.5  $\mu$ g of RNA polymerase. After 2 min, 10  $\mu$ g seminal plasmin was added in b (but not in a which served as the control), and the transcription continued. In c, 10  $\mu$ g seminal plasmin and 2.5  $\mu$ g RNA polymerase were incubated for 30 min. Other details were as in Fig. 1. In all the figures, A-D, the reaction was carried out in 0.1 ml and 20  $\mu$ l of the reaction mixture was used for estimation of radioactivity in RNA as described in Fig. 1.

**Fig. 4** Chromatography of the RNA polymerase and seminal plasmin complex on Sephadex G-75. RNA polymerase (20  $\mu$ g) was incubated without (○) or with (●) seminal plasmin (40  $\mu$ g) in Tris-HCl buffer (Fig. 1) in a total volume of 50  $\mu$ l, for 30 min at 37°C; 40  $\mu$ l of the mixture was then loaded on a Sephadex G-75 column (1  $\times$  9 cm). The column was eluted with the Tris-HCl buffer and 80  $\mu$ l fractions collected. The polymerase activity in each fraction (10- $\mu$ l aliquot) was assayed as in Fig. 1, in a total volume of 0.05 ml using poly(dA-dT) as the template;  $^{14}$ C-UTP (4,000 c.p.m. nmol $^{-1}$ ) and ATP were used as the substrates, and the reaction was carried out for 10 min after the addition of the substrate mix.

That seminal plasmin inhibits the formation of the first inter-nucleotide linkage (the initiation step in transcription), at least in the case of certain promoters in T7 DNA recognised by the RNA polymerase *in vitro*, was shown by the following experiment done essentially as described in Fig. 1. RNA polymerase (25  $\mu$ g ml $^{-1}$ ) was incubated for 30 min without seminal plasmin (the control), or with seminal plasmin 50  $\mu$ g ml $^{-1}$ ; T7 DNA (1.2 pmol ml $^{-1}$ ) was then added, the incubation continued for another 10 min, and the transcription started by addition of a mixture of ATP and  $^{14}$ C-UTP. After allowing transcription for 30 min, a 20- $\mu$ l aliquot from each sample was subjected to ascending chromatography on a paper strip (18  $\times$  2 cm) in water:saturated ammonium sulphate solution:2-propanol (18:80:2 v/v); 1 cm-wide strips were then cut and counted. This system allows separation of pppApU and the triphosphate precursors used<sup>3</sup>. The presence of seminal plasmin in the incubation mixture caused a 34% reduction in the radioactivity found in the pppApU spot. Seminal plasmin at the concentration used in this experiment inhibited transcription of T7 DNA by 70–85%.

The presence of the template from the start of the incubation mixture caused little change in the inhibitory effect of seminal plasmin on the transcription of templates such as poly(dT), but significantly reduced the inhibitory effect for other templates including poly(dI-dC) (Fig. 1G,H). The reasons for this difference are also not clear.

Seminal plasmin inhibited the transcription of poly(dA-dT) by RNA polymerase core enzyme to the same extent as that by the holoenzyme; no other template was tried with the core enzyme.

**Fig. 5** Fractionation by SDS-PAGE of seminal plasmin-RNA polymerase complex from a Sephadex G-75 column. The complex was formed by incubating seminal plasmin (90  $\mu$ g) with RNA polymerase (50  $\mu$ g) in 60  $\mu$ l of the transcription buffer for 30 min at 37°C, and chromatographed on a Sephadex G-75 column, as in Fig. 4. The polymerase-containing fractions 14–16 and 17–19, eluting in the exclusion volume, were pooled separately, lyophilised, and run on SDS-PAGE<sup>5</sup> using a 5% (top)–15% (bottom) discontinuous gradient slab-gel. RNA polymerase holoenzyme and seminal plasmin were run on the same gel as controls. 1, Seminal plasmin; 2, fractions 14–16 of Sephadex G-75 column; 3, fractions 17–19 of Sephadex G-75 column; 4, RNA polymerase holoenzyme.

**Fig. 6** Binding of seminalplasmin to DNA.  $^3\text{H}$ -poly(dA-dT) (2.4 nmol of dA-dT; 8,200 c.p.m.) (A) or  $^3\text{H}$ -poly(dT) plus poly(dA) (1.48 nmol of dT; 117,700 c.p.m.) (B) was incubated in 1 ml of Tris-HCl buffer (pH 7.9) containing 0.05 M NaCl and 10 mM  $\text{MgCl}_2$ , with the stated amount of seminalplasmin for 30 min at  $0^\circ\text{C}$ , and filtered through a Millipore membrane filter (0.45  $\mu\text{m}$ ). The filter was washed slowly with 5 ml of the ice-cold buffer, dried and counted.

Seminalplasmin also binds strongly to DNA (Fig. 6A, B), a maximum of 1 mol of seminalplasmin being bound per 8 base pairs in the case of poly(dA-dT). (The stoichiometry of interaction of seminalplasmin with poly(dT)·poly(dA) (Fig. 6B) could not be estimated, as the reaction mixture contained free poly(dA) in addition to the complex.) Apparently, this binding is not involved in the inhibition of transcription.

The precise mechanism, through which the binding of seminalplasmin to *E. coli* RNA polymerase leads to loss of enzyme activity remains unclear. It is also not known why seminalplasmin inhibits the transcription of certain templates such as poly(dT), T7 DNA and CT DNA, completely, while only a partial inhibition is observed with DNAs such as poly(dA-dT) containing a repeating dinucleotide sequence.

## Low tryptophan diet decreases brain serotonin and alters response to apomorphine

RATS fed on a low tryptophan diet since weaning have lower levels of brain serotonin than rats maintained on a control diet (18% casein diet)<sup>1,2</sup>. We have used such rats to investigate the role of the serotonergic system in the regulation of a behaviour primarily controlled by dopaminergic neurotransmission—apomorphine-induced stereotyped behaviour<sup>3–5</sup>. This behaviour, which is induced by psychomotor stimulant drugs, including apomorphine and amphetamine<sup>3–6</sup>, is repetitive, preservative behaviour that can be defined as the performance of an increasing rate of responses within a decreasing number of response categories<sup>6</sup>. In the rat, this is generally manifest as repetitive sniffing and motor movements, with repetitive licking and gnawing at higher drug levels. Although the mechanisms

controlling stereotyped behaviour are primarily dopaminergic, there are other modulatory influences, for example cholinergic and noradrenergic<sup>7,8</sup>. Apomorphine is thought to act by direct stimulation of dopamine receptors in the telencephalon<sup>9,10</sup>. There is some evidence that serotonergic mechanisms may be involved in stereotypy, because the integrity of the raphe nuclei is important for the expression of the stereotypy response produced by apomorphine and other agents<sup>11</sup>. We have found that reductions in brain serotonin (5-HT) produced by diet result in decreased stereotypy after apomorphine administration.

Weanling, male Sprague-Dawley rats were housed at six per cage and given free access to food and water. Half of the rats were fed a corn-based diet containing Masa Harina as the source of protein and carbohydrate (low tryptophan rats) and the other half were fed an 18% casein diet (control rats). Each diet contained a vitamin supplement that supplied adequate amounts of niacin. The full details of the method and diets used have been described elsewhere<sup>2,12</sup>. The rats were kept on these diets for at least 6 weeks and were rehoused in individual cages for at least 2 weeks before the start of the experiments.

On test days, rats were given doses (0.1–1.0 mg per kg, subcutaneously in the neck) of apomorphine HCl. Stereotyped behaviour (SB) was rated at 5-min intervals throughout the test session by experienced observers. The rating system was as follows: 0 = normal behaviour, inactive; 1 = normal behaviour, active; 2 = bursts of stereotyped sniffing, rearing or locomotion; 3 = continuous stereotyped sniffing, rearing or locomotion over a wide area of the cage; 4 = continuous stereotyped sniffing in one part of the cage; 5 = continuous SB with intermittent licking and gnawing; 6 = continuous SB with continuous licking and gnawing<sup>13</sup>. To assess differences between groups in the intensity of stereotypy, each rat's median score was determined, and pooled scores were analysed using the information statistic<sup>14,15</sup>. To assess differences between groups in the duration of stereotypy, each rat's rating for the final 5 min of the test was evaluated (stereotypy or no stereotypy), and pooled scores were then analysed using the information statistic.

**Table 1** Number of low tryptophan or control rats showing normal behaviour or stereotyped behaviour at the final rating period of the test

Dose of apomorphine (mg per kg, s.c.)	Diet group	No. of rats showing normal behaviour	No. of rats showing stereotyped behaviour
0.1	LT	9	1
	C	5	5
0.2	LT	8	2
	C	2	8
0.5	LT	6	4
	C	1	9
1.0	LT	8	1
	C	3	7

LT, low tryptophan; C, control. At each dose of apomorphine, the differences between the two groups are significant at least at the  $P < 0.05$  level.

The apomorphine-induced stereotypy of low tryptophan rats was significantly attenuated compared with control rats (Table 1). In addition, at the 0.2-mg per kg dose of apomorphine, the low tryptophan rats showed less intense stereotypy than control rats (Fig. 1). These differences in intensity and duration of stereotypy between the two diet groups were abolished by pretreatment with L-tryptophan at 50.0 mg per kg, indicating that the reduction in stereotypy shown by low tryptophan rats was mediated by the serotonergic system.

After the behavioural experiment, a biochemical study was conducted to ensure that low tryptophan rats had decreased levels of brain 5-HT. Rats were decapitated at between 1000 h and 1200 h and brains were removed quickly, bisected midsagittally and frozen on dry ice. One half of each brain was assayed for serotonin<sup>16–18</sup>. Our results confirmed reports that

**Fig. 1** Stereotypy after administration of apomorphine (0.2 mg per kg, given subcutaneously) in low tryptophan (hatched columns) and control (black columns) rats. Categories of stereotypy rating are on the abscissa. The frequency of each rating is summed over the test session.

rats maintained on a low tryptophan diet (corn diet) for 5 weeks have lower levels of brain 5-HT than rats maintained on a control diet (18% casein diet)<sup>1,2</sup>:  $588 \pm 31$  ng g<sup>-1</sup> compared with  $675 \pm 19$  ng g<sup>-1</sup> (means  $\pm$  s.e., significant at the  $P < 0.05$  level ( $t = 2.41$ , Student  $t$  test)).

In experiments which replicated and extended the findings of the first study, we investigated the effects of a novel 5-HT agonist MK-212 and of quipazine on apomorphine-induced stereotypy in low tryptophan rats<sup>19-21</sup>. Again, the differences between the two groups in intensity and duration of stereotypy were abolished when the low tryptophan rats were treated with either MK-212 (3.0 mg per kg, intraperitoneally) or quipazine (5.0 mg per kg, intraperitoneally).

Finally, we investigated the effects of low tryptophan diet on another response thought to be mediated, at least in part, by dopaminergic mechanisms—psychomotor stimulant-induced hypothermia<sup>22,23</sup>. The pattern of results for body temperature was similar to that obtained for stereotypy, in that low tryptophan rats showed a decrease in duration of hypothermic response after intraperitoneal administration of apomorphine at 5 mg per kg compared with control rats ( $F = 6.75$ ; d.f. 1, 16;  $P < 0.025$ ). Although the mean final hypothermic response under saline was the same for both diet groups (both  $+0.2$  °C), the apomorphine-treated control rats showed a significantly greater decrease in body temperature compared with the apomorphine-treated low tryptophan rats (means  $-1.3$  and  $-0.1$  °C, respectively). These results indicate that changes in brain serotonin can affect drug-induced hypothermia.

In conclusion, it seems that the decreased stereotypy response is associated with the decreased levels of brain 5-HT of rats reared on a low tryptophan diet. These findings show that while stereotyped behaviour is primarily mediated by dopaminergic (DA) mechanisms, it can also be modulated by other neurotransmitters, including 5-HT. This DA-5-HT interaction has implications for models of psychosis based on stereotypy<sup>24</sup>. Further, this set of experiments demonstrates that diet can alter both neurotransmitter levels and behaviour.

These studies were supported by grants from NIH (AM-14228) and NASA (NGR-22-009-627). MK-212 was supplied by Merck. We thank Ms Pearl Shiu for technical assistance.

## Frequency-dependent selection due to kinetic differences between allozymes

ENZYME polymorphisms detectable by gel electrophoresis are common in populations of animals, plants and micro-organisms<sup>1-3</sup>. Often the enzymes coded for by alternative alleles differ in their kinetic properties<sup>4,5</sup>. Although the causes of enzyme polymorphism are much disputed<sup>5-7</sup>, there has been no systematic attempt to examine the possible selective consequences of kinetic differences between allozymes. We report here a theoretical study suggesting that in some circumstances kinetic differences lead to frequency-dependent selection, which is potentially capable of maintaining balanced polymorphism.

We consider first the simplest possible model of an enzymatically catalysed reaction

where E, S and P represent enzyme, substrate and product, respectively, and  $k_{+1}$ ,  $k_{+2}$ ,  $k_{-1}$  and  $k_{-2}$  are velocity constants. If steady-state conditions prevail, and the product is not accumulating, the velocity of the reaction is

$$v = \frac{V_{\max}[S]}{K_m + [S]} \quad (1)$$

where  $V_{\max} = k_{+2}[E]$  and  $K_m = (k_{-1} + k_{+2})/k_{+1}$ . The equilibrium constant of the reaction, which is independent of the enzyme, is

$$K_{eq} = \frac{k_{+1}k_{+2}}{k_{-1}k_{-2}} \quad (2)$$

If the concentration of enzyme remains constant, the only way that  $V_{\max}$  can be increased is by an increase in  $k_{+2}$ . In most circumstances, this will increase  $K_m$  (a compensating decrease in  $k_{-1}$  is unlikely because  $k_{+2}$  and  $k_{-1}$  both reflect the stability of the ES complex, and a compensating increase in  $k_{+1}$  is unlikely because of the constraint imposed by equation (2)). Thus, if there are two allozymes differing in their kinetic constants and one of them (A) has a relatively high  $V_{\max}$  (represented as  $V_H$ ), it is also likely to have a relatively high  $K_m$  ( $K_H$ ). The lower constants of the other allozyme (a) can be represented as  $V_L$  and  $K_L$ .

This theoretical prediction is supported by the available experimental observations on the kinetic constants of alterna-

tive allozymes (Fig. 1). Although the data are sparse, they demonstrate a clear tendency for the values of  $V_{\max}$  and  $K_m$  to vary together. This being so, at a given concentration of substrate,  $[S]$ , the ratio of the velocities generated by the two allozymes will be

$$R = \frac{v_A}{v_a} = \frac{V_H(K_L + [S])}{V_L(K_H + [S])} \quad (3)$$

When  $[S]$  is very large relative to the values of  $K_m$ , this approximates to

$$R' = \frac{V_H}{V_L}$$

However, when  $[S]$  is very small relative to the values of  $K_m$ , it approximates to

$$R'' = \frac{V_H K_L}{V_L K_H}$$

which is necessarily smaller than  $R'$ . At intermediate concentrations of  $S$ , the value of  $R$  lies between these two extremes. Thus, the relative velocity of the reaction catalysed by  $A$  is greater at high substrate concentrations than at low concentrations.

This conclusion is not restricted to a single-substrate reaction, nor to the unrealistic assumption that the reaction proceeds through only one intermediate. It follows from any system in which an increase in  $V_{\max}$  is associated with an increase in  $K_m$ . It seems that the two constants can increase together even in complex systems (see Fig. 1 and, for formulae, ref. 8).

If the rate of the reaction contributes monotonically to the relative fitness of the organism (that is, if the reaction is rate limiting for some vital process, and if the selective value is a monotonically increasing function of velocity), then individuals with the  $A$  enzyme will be relatively fitter when substrate concentrations are high than when they are low.

To study the effect on selective values of varying the numbers and frequencies of individuals, it is convenient to assume that there is in the environment a substance, either the substrate or a precursor of it, whose effective rate of uptake by the organism is dictated by the velocity of the reaction. In this case, an increase in the number of organisms acts as a proportional increase in  $[E]$ ,

**Fig. 1** Plot of relative maximum activities ( $V_1/V_2$ ) against relative  $K_m$  values ( $K_1/K_2$ ) in comparisons between allelic enzyme variants occurring in natural polymorphisms. The data come from five separate studies:  $\circ$ , ADH in *D. melanogaster* (D. Thatcher, unpublished data);  $\square$ , lactate dehydrogenase (LDH) in *Fundulus heteroclitus*<sup>24</sup>;  $\blacktriangle$ , penicillinase in *Bacillus licheniformis*<sup>25</sup>;  $\bullet$ , glucose-6-phosphate dehydrogenase in man<sup>26</sup>;  $\blacksquare$ , LDH in *Salmo gairdneri*<sup>27</sup>. The several symbols for a single enzyme represent values using different experimental conditions, either various temperatures (LDH) or substrates (ADH and penicillinase), and they are not independent of each other. All the measurements were made on purified enzymes. Symbols in the upper right and lower left quadrants support the proposed relationship.

**Fig. 2** The results of simulating the relative amount of substrate consumed, or product produced ( $P$ ), during development per individual plotted against the frequency of allele  $A$  in a population with Hardy-Weinberg genotypic proportions. The model assumes kinetic constants approximating those found empirically for the ADH polymorphism in *D. melanogaster* (ref. 13 and D. Thatcher, unpublished). The values used are  $A = Adh^F$ :  $V_{\max} = 900 \text{ pM min}^{-1}$ ,  $K_m = 0.01 \text{ M}$ ;  $a = Adh^S$ :  $V_{\max} = 450 \text{ pM min}^{-1}$ ,  $K_m = 0.005 \text{ M}$ . The heterozygote is assumed to contain only the two homodimers (because of the absence of information about the kinetic constants of the heterodimer). Development from egg to pupa is divided into 1,000 intervals of 10 min each. The amount of substrate (ethanol) consumed in each time interval is calculated by converting the rate equation (1) to a difference equation, and entering the appropriate values of substrate and enzyme concentrations. The enzyme concentrations per fly are assumed to be equal in flies of all genotypes and to increase linearly through the larval period to 100 pM per fly. The substrate concentration is increased at each interval by 0.0005 M (as if ethanol is being produced continuously by yeast in the food medium) and reduced by the amount consumed by the larvae during the previous interval. Five sets of simulations are shown that differ only by the number of larvae per vial ( $N$ ), which is given for each set.

and therefore in  $V_{\max}$  (without a concomitant increase in  $K_m$ ). Simultaneous proportional increases in  $V_H$  and  $V_L$  will not alter the values of  $R'$  and  $R''$ . However, if the supply of precursor or substrate is sufficiently limited, increases in  $V_H$  and  $V_L$  will accelerate its removal from the environment and will significantly reduce  $[S]$ . Consequently, they will shift the system away from the state represented by  $R'$ , towards that represented by  $R''$ . In other words, an increase in the number of organisms will tend to reduce the selective value of  $A$ . The selection will be density dependent.

The selection will also be frequency dependent. An increase in the number of individuals carrying the more active  $A$  enzyme will have a greater effect on  $[S]$  than an equivalent increase in the number of individuals carrying  $a$ . At high frequencies of  $A$  its selective value will be less than at low frequencies. This is frequency-dependent selection, which is potentially capable of maintaining a balanced polymorphism (see, for example, ref. 9), and follows directly from the difference between the two allozymes in their  $V_{\max}$  and  $K_m$ . Figure 2 demonstrates that the frequency-dependent effect can be appreciable.

The existence of frequency-dependent selection in the conditions assumed leads us to enquire whether it provides a general explanation for selectively maintained enzyme polymorphisms. The generality of the assumptions must, therefore, be examined critically.

The first assumption is that the rate of reaction contributes monotonically to fitness. It implies that the reaction is rate limiting to some vital process, and thus excludes non-rate-limiting enzymes. However, although at any instant only one reaction in a pathway can be rate limiting, in a changing environment several or many may be successively so. There are, of course, situations in which an 'optimal' velocity can be exceeded, when overactivity is disadvantageous. In such situations, frequency-dependent selection of the balancing kind is less likely to occur, but it is not excluded.

The second assumption is that the removal of precursor or substrate from the environment is dictated by the velocity of the reaction. This again implies that the reaction is rate limiting, but also that it takes part in a pathway concerned with the uptake of an external substance. Enzymes catalysing reactions in deeply embedded internal pathways are not expected to be subject to this kind of frequency-dependent selection.

The third assumption is that the available supply of precursor or substrate is low enough to be significantly altered by changes in the rate of the reaction. This will certainly occur when there is ecological competition for the precursor or substrate (for example, as food), because such competition necessarily implies a shortage of the resource, but it can also occur in other circumstances when the resource is not crucial to the survival of the population. The depletion, if it is to produce frequency-dependent selection, must not be merely local to the individual; it must spread to affect others. This can occur most effectively when the substance is freely diffusible, and when the organisms are crowded in a fluid environment. The frequency-dependent selection is most likely to act on organisms that obtain their food in solution (as, for example, do many microorganisms, dipteran larvae and the roots of plants). It is less likely to act on animals that ingest particulate food.

The crucial question is whether unused precursor or substrate is returned to the environment in a form available to other organisms. Among herbivores and carnivores this return may take place through the faeces, but there will usually be a delay before the substance is once more available for consumption. Such a delay will certainly tend to destabilise the system.

Both intuition and simulation suggest that the frequency-dependent effect of substrate diminution will be strongest when the concentration of substrate approximates to the  $K_m$  of the enzyme. This situation is probably common. There seem to be long-term evolutionary pressures adjusting the  $K_m$  values of enzymes towards the average concentrations of their substrates<sup>10</sup>.

Finally, it is necessary to consider how often the frequency-dependent selection will actually, rather than potentially, maintain a polymorphism. Figure 2 shows a model derived from the kinetic constant of alcohol dehydrogenase (ADH) in *Drosophila melanogaster*, in which  $V_{max}$  and  $K_m$  seem to be roughly proportional to each other. Although the selective advantage of the more active enzyme falls as its frequency increases, it is nevertheless always superior to the less active enzyme. If a genuine balance is to be achieved there must be some additional disadvantage associated with a higher  $V_{max}$ . This disadvantage may be a disproportionate increase in  $K_m$ . The more active allelic enzyme is sometimes less stable (ADH<sup>11-13</sup> and xanthine dehydrogenase<sup>14</sup> in *D. melanogaster*). Enzymes are often stabilised by the binding of substrate, so that when the concentration of substrate is low an enzyme with a higher  $K_m$  may be more liable to degradation.

The hypothesis that enzyme polymorphism can be a consequence of differences in kinetic parameters is attractive for several reasons. First, it offers an explanation of polymorphism that may be widely applicable. Second, the present model leads to several specific and testable predictions. For example, it predicts that rate-limiting enzymes should be more often polymorphic than non-rate-limiting, that enzymes with external substrates should be more often polymorphic than those intimately associated with the metabolic pathways of homeostatic organisms, and that enzymes with pervasive and freely diffusible substrates should be more often polymorphic than those with scarcer and less mobile substrates. There is already some support for these predictions. Regulatory enzymes, which are by implication rate limiting, have been claimed to have higher average levels of polymorphism than non-regulatory enzymes<sup>15</sup> (but see ref. 16). Enzymes with external variable substrates are more polymorphic than those with internal constant substrates<sup>15</sup>. Invertebrates generally have higher levels of polymorphism than vertebrates<sup>2</sup>, which have a better-developed internal homeostasis. Frequency-dependent selec-

tion has been reported to act on allozymic genotypes at two loci in *D. melanogaster* coding for enzymes with external substrates<sup>17-19</sup>.

The third attraction of the 'kinetic' hypothesis is that it offers a closer integration between the theories of enzymology, population genetics and ecology. We note, in this context, that selection for an increase in  $V_{max}$  resembles the  $r$ -selection of the ecologists<sup>20</sup>, that selection for a decrease in  $K_m$  resembles  $k$ -selection, and that our model is mathematically similar to the models of inter- and intraspecific competition put forward by Stewart and Levin<sup>21</sup> and by de Jong<sup>22</sup>. Ainsley<sup>23</sup> has suggested that kinetic differences in the ability of allelic enzymes to remove toxins can give rise to frequency-dependent selection, and his argument is similar in principle to our own.

In conclusion, it seems that biochemical differences (in  $V_{max}$  and  $K_m$ ) between allelic variants of enzymes can, in some circumstances, lead directly to frequency- and density-dependent selection. Such differences may be responsible for maintaining a significant proportion of enzyme polymorphisms, particularly among organisms taking up dissolved food.

We thank Drs Harry Flint, Bruce Middleton and David Thatcher for helpful comments, Dr Thatcher for allowing us to quote his unpublished data, and the SRC, MRC and the NATO Fellowship Program of the NSF for financial support.

## Amino acid substitutions in two functional mutants of yeast alcohol dehydrogenase

A METHOD has been developed<sup>1-3</sup> for selecting mutants of the structural gene for the constitutive alcohol dehydrogenase of the yeast *Saccharomyces cerevisiae*. These mutations alter but do not destroy the function of the enzyme. We report here the amino acid substitutions in two of these mutants, and examine the probable effects of these substitutions on enzyme structure and function. This is possible since the amino acid sequence<sup>4</sup>, isozyme differences<sup>5</sup> and possible subunit conformation<sup>6</sup> of the protein are known.

**Fig. 1** Autoradiogram of neutral peptides separated by electrophoresis at pH 1.9. Fluorescent peptides are indicated by dashed lines. Samples are: *a*, mutant C-40; *b* and *d*, wild-type isozyme I; *c*, mutant S-AA-5.

The mutants were isolated from strain XW517-2D, a mating type. This strain carries a mitochondrial lesion rendering it incapable of aerobic respiration (cytoplasmic petite). In common with other petite strains, the only alcohol dehydrogenase found in the cytoplasm of this strain is the constitutive ADH-I, coded by the gene *adc*<sup>7</sup>. When grande strains of yeast, which are capable of aerobic respiration, are exposed to allyl alcohol, the majority of resistant mutants are ADH-negative<sup>1,8</sup>. This prevents formation of the poisonous aldehyde acrolein from the allyl alcohol, which is by itself harmless. In contrast, petite allyl alcohol resistant mutants must continue to exhibit ADH activity, and their source of resistance has been shown in three cases<sup>2,3</sup> to be due to shifts in the intracellular concentrations of NAD and NADH. A relative increase in the latter lowers the

equilibrium concentration of acrolein in the cell. Kinetic alterations observed in the mutant enzymes affect binding constants and cooperativity, and are compatible with the observed shifts<sup>3</sup>.

Two of these mutants, S-AA-5 and C-40, were analysed. Both mutant enzymes are more basic than the wild-type form, as deduced from electrophoretic mobilities. They also exhibit kinetic differences. The enzymes were purified using affinity chromatography on AMP-Sepharose and ion-exchange chromatography on DEAE-cellulose<sup>5,9</sup>. Proteins were reduced and alkylated with iodo[<sup>14</sup>C]acetate in 6 M guanidine-HCl<sup>5</sup>. Digestion of 1 mg samples of the wild-type and mutant forms was carried out with trypsin. The mixture of peptides was separated on paper by multidimensional electrophoresis and chromatography<sup>10</sup>. The patterns were examined by autoradiography, fluorescence in UV light, and by staining with Cd-ninhydrin<sup>11</sup>.

In both mutants, alterations were immediately apparent. There is only one radioactive neutral<sup>12</sup> tryptic peptide in ADH-I, and it is also the only fluorescent neutral peptide. It extends from position 39 to 59, including a histidine at position 44 (ref. 4). In S-AA-5, this peptide was absent, and instead two others were detected, a radioactive and a fluorescent fragment (Fig. 1). On staining with Cd-ninhydrin, the fluorescent peptide took a yellow colour, suggesting that it might now begin with Thr 45. This was confirmed by analysis of peptides isolated from 15 mg of the purified enzyme. The results, given in Table 1, show that the two new peptides comprise positions 39–44 (peptide 1) and positions 45–59 (peptide 2). The alteration in S-AA-5 was therefore His 44 → Arg.

The basic peptide beginning at position (315) in ADH-I, Ser-Pro-Ile-Lys<sup>4</sup>, was missing in mutant C-40, and replaced by two basic dipeptides, which on analysis (Table 1) proved to be Ser-Arg and Ile-Lys. The alteration in this mutant was therefore Pro(316) → Arg. In each mutant enzyme, the increased basicity and the extra tryptic cleavages are explained by the substitution.

The tertiary structure of the dimeric horse liver ADH has been determined to 2.4 Å resolution<sup>13</sup>. Although the yeast enzyme is a tetramer and has a highly dissimilar amino acid sequence, there is much evidence<sup>6</sup> to suggest that the two proteins have a largely conserved subunit conformation. Therefore, it is reasonable to analyse the effects of the mutations in the yeast enzyme by examining equivalent positions in the horse protein.

**Table 1** Data for the extra tryptic peptides in the mutants S-AA-5 and C-40

Mutant	S-AA-5		C-40	
	1 (radioactive)	2 (fluorescent)	1	2
Electrophoretic mobility at pH 6.5 <sup>12</sup>	0	0	-0.63	-0.63

N-terminus	Tyr	Thr	Ser	Ile

**Fig. 2** Diagram of the polypeptide backbone in horse liver alcohol dehydrogenase. The positions corresponding to the exchanges in the mutants S-AA-5 and C-40 are indicated.

Of the two mutational changes, the His → Arg substitution in S-AA-5 has the most clearcut effect. The position is shown in Fig. 2, and corresponds to Arg 47 in the horse liver enzyme. This residue forms a salt linkage with the pyrophosphate moiety of the NAD<sup>13,14</sup>. The substitution is thus one which would be expected to shift the binding characteristics of the cofactor away from those of the yeast and towards those of the liver enzyme.

As histidine may be less ionised than arginine at physiological pH, this linkage could be weaker in the yeast enzyme, resulting in a higher  $K_m$ . This is in fact the case. The  $K_m$  values for NAD for the yeast<sup>2</sup> and mammalian<sup>15</sup> enzymes are 240 and about 10 mM respectively at pH 8.8. For NADH they are 140 and about 10 mM, respectively. In mutant S-AA-5, the  $K_m$  values for both NAD and NADH have been reduced to 60 mM, consistent with the expected effect of the substitution. As the reduction in  $K_m$  is not as great as in the mammalian enzyme, other substitutions must also play a part. This is compatible with the many differences observed in other residues involved in NAD binding<sup>14</sup>. This mutant also shows a loss of positive cooperativity in the reaction ethanol  $\rightarrow$  acetaldehyde<sup>2,3</sup>. The structural reason for this is not apparent, as the nature of the interactions in the quaternary structure are unknown.

The effect of mutant C-40 is more difficult to understand. The substitution Pro (316)  $\rightarrow$  Arg occurs at a distance from both the active site and the known region of subunit interaction in the horse enzyme (see Fig. 2), yet this mutant shows alterations in both cooperativity and substrate binding. The  $K_m$  values for ethanol and acetaldehyde have been raised fivefold and twofold respectively, while those for NAD and NADH remain unchanged<sup>3</sup>. The differences appear significant even if the absolute values for the wild-type enzyme are not in agreement with those from other investigations<sup>16,17</sup>.

The substitution occurs in the catalytic domain at a point corresponding to position 346 of the horse liver enzyme. This is at a turn between an extended structure along the inter-domain cleft, and a superficial strand of a  $\beta$ -pleated sheet region<sup>13</sup>. The substitution may influence the turn. It may also increase the spacing between the domains. With unaltered central inter-domain connections, this might restrict the pocket for the substrate and hence increase the  $K_m$  values. Alternatively, the substitution may affect interactions within the quaternary structure of the enzyme. The same region shows a number of differences in closely related isozymes (positions 178, (313), (337) and (338))<sup>4,5</sup>. The lysine residue equivalent to Lys 228 in the horse liver enzyme, modification of which can increase the turnover number<sup>18</sup>, is also nearby, as well as a substitution (Ala 230  $\rightarrow$  Pro) in a variant form of human liver alcohol dehydrogenase<sup>19</sup>.

The two mutants analysed in this study are the first for which the amino acid substitutions have been determined. Many other independent allyl alcohol-resistant mutants have also been produced by selection. The present results show that such mutants do not necessarily represent changes at the same point in the molecule, not even when electrophoretic mobilities are similar (S-AA-5 showed 86% and C-40 87% of the mobility of the wild-type enzyme at pH 8.6). There is therefore strong reason to suppose that amino acid substitutions at additional positions will explain many of the other functional mutants of ADH-I, and that their determination will cast further light on the function of the molecule.

We thank Julia Phelps for technical assistance and Carl-Ivar Brändén for the diagram and for discussions. This work was supported by the Swedish MRC (project 13X-3532) and the US PHS. C.W. was the recipient of a grant from the John Simon Guggenheim Memorial Foundation.

## Human complement C4 locus is duplicated on some chromosomes

WE have described genetic polymorphism of the fourth component of human complement (C4) and postulated that it was determined by an autosomal locus close to *HLA-B* on chromosome 6 (refs 1, 2). From familial and population studies of the electrophoretic C4 patterns, O'Neill *et al.*<sup>3</sup> postulated that there are two C4 loci in all individuals, and that C4° alleles occur with high frequency at both. It was further shown that the blood groups Chido (Ch) and Rodgers (Rg) are closely associated with certain C4 types and indeed represent antigenic determinants on C4 molecules<sup>4</sup>, probably on the C4d part<sup>5</sup>. In this report we have used immunochemical methods to show that the C4 locus is definitively duplicated at least on some chromosomes. The implications are that the locus is either duplicated on all chromosomes and C4° alleles occur frequently at both, or alternatively, that the locus is duplicated on some chromosomes only.

High-voltage agarose electrophoresis and immunofixation/haemolytic assay reveal several different C4 phenotypes. Familial studies of the segregation of C4 phenotypes have shown that there are three main C4 haplotype products (not phenotypes): a slow four-band 'short' pattern (S), a fast four-band short pattern (F), and a seven-band 'long' pattern including all the S and F bands (F<sub>1</sub> or FS)<sup>2</sup>. The most common of several rare haplotype products is a four-band short pattern (M) migrating slightly anodal to S. The S and M haplotypes are ordinarily Ch<sup>+</sup>, Rg<sup>-</sup>, the F haplotypes Ch<sup>-</sup>, Rg<sup>+</sup>, and the F<sub>1</sub> or FS haplotypes Ch<sup>+</sup>, Rg<sup>+</sup> (O.B. *et al.*, in preparation).

We postulated that if the C4F<sub>1</sub> (Ch<sup>+</sup>, Rg<sup>+</sup>) haplotype product was a mixture of proteins coded for by two genes, it should be possible to separate the S (Ch<sup>+</sup>) protein from F (Rg<sup>+</sup>) with an appropriate antibody. If on the other hand, the haplotype product was coded for by one gene, an antibody directed at one part of the molecule should affect the electrophoretic migration rate of both the S (Ch<sup>+</sup>) and the F (Rg<sup>+</sup>) part of the haplotype product.

C4 typing of samples was carried out as described in detail previously<sup>2</sup>. Ch and Rg typing of serum (plasma) was carried out by an inhibition assay of anti-Ch/Rg and C4 low ionic strength (LIS) coated red blood cells (RBC) using an antiglobulin reaction with IgG (R.N., in preparation). The anti-Ch serum used, serum OO, was from a patient recently transfused with several units of Ch<sup>+</sup> whole blood. Using RBC coated with C4 from Ch<sup>+</sup> serum in LIS medium, the direct agglutination titre in saline medium of this serum was 2,048, and more than 50,000 with an antiglobulin technique using pure anti-IgG. An IgG fraction of the OO serum was used in the studies described below. The serum was fractionated on a Sephadex G-200 column. The vacuum-concentrated IgG fraction gave a direct agglutinin titre exceeding 5,000 in saline against Ch<sup>+</sup> C4-coated RBC, whereas the IgM fraction was negative.

Equal volumes of heparin plasma C4S (Ch<sup>+</sup>, Rg<sup>-</sup>) and the IgG fraction of serum OO, incubated for 1 h at 37°C, showed that the IgG fraction completely removed the electrophoretic C4S pattern from the plasma. The C4 pattern of C4F (Ch<sup>-</sup>, Rg<sup>+</sup>) did not change in the same conditions.

**Fig. 1** Electrophoretic C4 patterns before and after absorption with IgG fraction of an anti-Ch antiserum. 1: Control C4F/F plasma sample; 2: F/S plasma sample; 3: F/S plasma sample absorbed; 4: FS/M plasma sample; 5: FS/M plasma sample absorbed; 6: FS/F plasma sample; 7: FS/F plasma sample absorbed; 8: M/S plasma sample; 9: M/S plasma sample absorbed; 10: FS/S plasma sample; 11: FS/S plasma sample absorbed; 12: S/S plasma sample control.

Figure 1 shows our main results. The individuals studied are members of families whose *C4/Ch/Rg* haplotypes are fully mapped from segregation in three generations. To summarise the results: The OO IgG fraction in this experiment absorbed S from S plasma, MS from MS plasma, S from F<sub>1</sub>S plasma, S from F<sub>1</sub>F plasma, S and M from F<sub>1</sub>M plasma, and S from FS plasma. It did not absorb anything from F plasma. The control experiments exclude dilution and nonspecific degradation as causes of the observed results. We have therefore shown that the *C4* locus is indeed duplicated in some individuals, that is, on either one or both chromosomes in individuals segregating for the F<sub>1</sub> pattern. We therefore now recommend a change in nomenclature to haplotypes; a person homozygous for the two genes previously called F<sub>1</sub> would be of the haplotype *FS/FS* and a person heterozygous for one F<sub>1</sub> and one F or S would be either *FS/F* or *FS/S*.

The chromosomes not coding for long patterns may, however, still have only one *C4* locus, as the guinea pig seems to have, the only animal so far studied with similar techniques<sup>6</sup>. The postulate that all human chromosomes have two *C4* loci with a high frequency of *C4*<sup>o</sup> alleles<sup>3</sup> remains unproved. This hypothesis can probably only be tested when it is possible to approach the problem on the DNA or RNA level. The present findings suggest that duplication/non-duplication of the *C4* locus may be present as a polymorphism of its own in humans. One may speculate, of course, on the possible forces behind a polymorphism of this kind. Could a duplicated *C4* locus represent an evolutionary advantage in humans, and thus represent a trait occurring increasingly frequently in the human race?

This study was in part supported by the Norwegian Council for Science and the Humanities, and the Anders Jahre's Foundation. The anti-Rg serum was from Dr C. Giles.

## Sequence of the 5'-end of *Strongylocentrotus purpuratus* H2b histone mRNA and its location within histone DNA

EXTENSIVE DNA sequence analysis of the cloned histone gene repeat unit from the sea urchin *Strongylocentrotus purpuratus* has identified the five histone protein coding sequences<sup>1-3</sup> (I.S., unpublished). R-loop and heteroduplex mapping strongly suggest that the sea urchin histone genes contain no intervening sequences<sup>4</sup>. In addition to the protein coding sequences the corresponding histone mRNAs each contain about 100 extra nucleotides<sup>4,5</sup>. The location of these additional sequences in relation to the coding sequences is not certain. It is of interest to map the mRNA termini within the known DNA sequence because this information may help to identify transcriptional and translational control elements. Direct nucleotide sequence analysis of RNA can be carried out by enzymatic, base-specific cleavage of end-labelled RNAs<sup>6,7</sup>. However, 5'-end labelling of mRNAs involves several enzymatic reactions ('decapping', dephosphorylation and phosphorylation) that require nuclease-free enzyme preparations<sup>8</sup>; furthermore, the RNA to be sequenced must be homogeneous. Indirect sequencing analysis of RNA can be obtained from its complementary cDNA. RNA has been sequenced in this way using a chain termination method with dideoxytriphosphates<sup>9</sup>, synthetic primers and purified mRNA templates<sup>10-12</sup>. Alternatively, end-labelled restriction fragments have been used to prime synthesis of cDNA on homogeneous<sup>13,14</sup> and partially purified<sup>15,16</sup> mRNA templates followed by either chemical<sup>17</sup> or enzymatic<sup>9</sup> sequencing of the resulting cDNA. Our approach is similar and shows that prior purification of the RNA template is unnecessary. We present here the 5'-terminal sequence of *S. purpuratus* H2b mRNA, derived from purified H2b mRNA as well as from total polysomal RNA, using the chain termination method<sup>9</sup> adapted for RNA sequencing. We also determine its location within the histone DNA sequence.

A short DNA restriction fragment, known to be located in the H2b protein coding region, was used as a primer for RNA-directed DNA synthesis. During an initial hybridisation step in which DNA/RNA hybridisation is favoured over DNA/DNA hybridisation<sup>18</sup>, the appropriate DNA strand binds to its complementary RNA sequence as a primer, and in this way selects the RNA template, which is then copied by reverse transcriptase in the presence of the four dideoxy chain terminators.

As shown in Fig. 1, we used as a primer a 51-base pair DNA fragment which is located in the NH<sub>2</sub>-terminal end of the H2b coding region and is generated by *AluI* and *HaeIII* restriction endonucleases (New England Biolabs). The 3'-end of this priming DNA strand is located 10 bases downstream from the protein initiation codon. The fragment is short enough for the elongated chain-terminated DNA to be easily separated on the sequencing gels. This DNA fragment was obtained by endonuclease digestion of pRC39 (ref. 4), a plasmid which contains a completely sequenced *BamI/EcoRI* restriction fragment (1,016 base pairs) encompassing the H2b histone gene. The digestion products were separated on 8% (1/30 cross-linked) polyacrylamide gels. This homogeneous fragment was used to prime DNA synthesis by reverse transcriptase on both purified H2b mRNA and unpurified, total polysomal RNA as described below. In parallel with the RNA template we also used a DNA template, the *BamI/EcoRI* restriction fragment. The strands of this fragment were separated by electrophoresis on a 5% (1/60 cross-linked) polyacrylamide gel<sup>19</sup> after denaturation in 50% dimethyl sulphoxide at 90 °C for 3 min (ref. 20). The faster-moving non-coding strand which has the same 5'-3' orientation as the mRNA was used as the template.

Five equivalents (10 pmol) of the double-stranded DNA primer fragment were denatured and hybridised to the

**Fig. 1** Nucleotide sequence of the 5'-end of histone H2b mRNA and its location within the DNA sequence of *S. purpuratus*. **a**, *Alu*I and *Hae*III restriction endonuclease map of the cloned *Bam*I/*Eco*RI restriction fragment containing the H2b coding region (thicker horizontal line). Open boxes indicate the locations of nucleotides common to all sequenced *S. purpuratus* histone genes. Nucleotides are numbered by reference to the first nucleotide of the initiation codon. The DNA template for reverse transcriptase is the non-coding strand of the *Bam*I/*Eco*RI fragment. The primer DNA (p) is the *Alu*I/*Hae*III fragment; its location and 3'-5' orientation is indicated. **b**, 5'-terminal nucleotide sequence of H2b mRNA (bottom line) deduced from the cDNA sequence of: (A) purified H2b mRNA; (B), polysomal RNA; (C), the non-coding DNA strand of the *Bam*I/*Eco*RI restriction endonuclease fragment. Only the positively identified nucleotides are shown. In the double-stranded DNA sequence (C) the lower strand was determined in this experiment whereas the upper strand served as a template. The initiation codon and the common nucleotides PyCATTCpu are boxed. The 'cap' structure of the mRNA is indicated by the black box.

following: (1) One equivalent (2 pmol) purified H2b mRNA, assuming that the length of the mRNA is 500 bases<sup>4,5</sup>. The mRNA was purified by hybridising total polysomal RNA extracted from early blastula stage *S. purpuratus* embryos to an excess of pRC39 DNA immobilised on cellulose as previously described<sup>21</sup>. The eluted RNA is of a single size, as judged by polyacrylamide gel electrophoresis, after 3'-end labelling with RNA ligase and <sup>32</sup>P-pCp (ref. 7 and I.S., unpublished). (2) One equivalent (2 pmol) H2b RNA in 125 µg total polysomal RNA assuming 0.25% of the polysomal RNA represents H2b mRNA. (3) One equivalent (2 pmol) single-stranded DNA of the *Bam*I/*Eco*RI restriction fragment.

DNA/RNA hybridisation was carried out in 80% formamide, 2 × SSC at 50 °C for 2 h at primer and template concentrations of 1 µM and 0.2 µM, respectively. The conditions for DNA/DNA hybridisation were as described elsewhere<sup>9</sup> except that the primer was separately denatured at 100 °C for 3 min before hybridisation. Denatured primer and single-stranded template were annealed at 68 °C for 30 min at concentrations of 0.8 µM and 0.16 µM, respectively.

The chain-terminated polymerisation reactions were carried out with reverse transcriptase as described in the legend to Fig. 2. Each set of reactions included a control mixture without dideoxy chain terminators<sup>13</sup> to identify full-length transcripts and possible artefactual bands on the sequencing gel caused by nonspecific termination during the polymerisation reactions. The <sup>32</sup>P-labelled reaction products were separated on thin 7 M urea-8% polyacrylamide (1/30 cross-linked) gels<sup>22</sup> and visualised by autoradiography.

Figure 2 shows autoradiographs of the sequencing gels. The three panels show the reverse transcriptase transcription products derived from purified DNA (a), polysomal RNA (b) and DNA templates (c). The sequences of the RNA-dependent transcripts (Figs 1bA, B, 2a, b) are identical to the sequence derived from the DNA template. The sequenced portion of the 5'-end of the H2b mRNA is therefore co-linear with the corresponding sequence of the cloned sea urchin histone genes<sup>3</sup> and does not contain any nucleotide insertions or deletions. This

co-linearity extends beyond the nontranslated leader sequence, at least to nucleotide 64 of the protein coding region (data not shown). The sequence derived from the DNA template (Figs 1bC, 2c) confirms the sequence data previously reported<sup>3</sup>.

Sequences derived from the RNA template are ambiguous at certain positions, perhaps related to secondary structure or site-specific degradation of the RNA. Such nonspecific stops do not occur on the DNA template. The single-stranded DNA template which has the same 5'-3' orientation as the H2b mRNA was sequenced in parallel with the mRNA template. This side by side sequencing facilitates the determination of bases in these ambiguous positions. The DNA template, which is longer than the homologous mRNA, also serves as a control for nonspecific termination (see below). It is not necessary to determine beforehand the orientation (coding or non-coding) of the two separated DNA strands. They can both be used as templates in separate reactions and only the sequence derived from the non-coding strand serves as a reference.

It is interesting that the DNA sequence derived from purified H2b mRNA contains more nonspecific termination events than that derived from total polysomal RNA. These nonspecific stops are clustered (Figs 1b, 2a, b) and might be a result of secondary structure in the RNA template which is more pronounced in purified RNA.

Whereas the first 20 nucleotides of the RNA-dependent transcript can be read unambiguously, the first 4 nucleotides of the reaction with the DNA template are unreadable. They are probably obscured by internally labelled primer molecules. In the RNA-dependent reactions the primer is not labelled because of the presence of actinomycin D. As the purified H2b mRNA was isolated by hybridisation in vast DNA excess, contaminating DNA sequences homologous to the mRNA might be present and available as a template. Actinomycin D was thus included to ensure the exclusive use of RNA templates by reverse transcriptase.

Both RNA-dependent sequences (Fig. 2a, b) stop 71 bases upstream from the protein initiation codon (Fig. 1). Although we cannot exclude the possibility that reverse transcriptase stops

**Fig. 2** Autoradiographs of sequencing gels showing the chain-terminated transcription products of the purified H2b mRNA (a), unpurified H2b mRNA (b) and the DNA (c) templates. Electrophoresis was on 8% (1/20 cross-linked) thin polyacrylamide gels<sup>22</sup> containing 7 M urea, 100 mM Tris-borate, pH 8.3, 1 mM EDTA at 1,000 V, constant power. Sections of three gels, electrophoresed for different times, are shown, overlapping nucleotides are bracketed. The nucleotides are numbered by reference to the first nucleotide of the initiation codon. DNA/RNA hybrids were prepared as follows: 10 pmol primer DNA was dissolved in 9  $\mu$ l 90% formamide (MC/B), denatured for 5 min at 40 °C and transferred to silanised Eppendorf tubes containing 2 pmol of the dried H2b mRNA template. The solution was adjusted to 2 $\times$ SSC, 80% formamide by addition of 1  $\mu$ l 20 $\times$ SSC and hybridisation was carried out for 2 h at 50 °C. (1 $\times$ SSC = 0.15 M NaCl, 0.015 M sodium citrate). The formamide was diluted with 20  $\mu$ l 2 $\times$ SSC and the hybrids precipitated with 100  $\mu$ l ethanol, washed twice with 80% ethanol and dissolved in 12  $\mu$ l 1.66 $\times$ H buffer. (H = 50 mM NaCl, 34 mM Tris, pH 8.3, 6 mM MgCl<sub>2</sub>, 5 mM dithiothreitol). DNA/DNA hybrids were prepared in sealed capillaries in a total volume of 12  $\mu$ l 1.66 $\times$ H buffer as described in the text. The RNA sequencing reactions were carried out in a total volume of 5.25  $\mu$ l in silanised Eppendorf tubes. Each reaction contained: 2  $\mu$ l hybrids in 1.66 $\times$ H buffer; 1  $\mu$ l dNTPs [500  $\mu$ M each of dATP, dCTP, dGTP (Sigma) and 85  $\mu$ M (100 Ci mmol)<sup>-1</sup> [ $\alpha$ -<sup>32</sup>P]-TTP (Amersham)]; 1  $\mu$ l 1 $\times$ H buffer containing 3 units reverse transcriptase from avian myeloblastosis virus (Life Sciences); 1  $\mu$ l of either 1 mM ddATP, 0.5 mM ddCTP, 0.5 mM ddGTP, 0.1 mM d(d)TTP (PL Biochemicals) or H<sub>2</sub>O and 0.25  $\mu$ l actinomycin D (1 mg ml<sup>-1</sup>) in 50% ethanol. In practice, a pre-mix containing hybrids, dNTPs and actinomycin D (Sigma) was added to the individual dideoxynucleotides, followed by the enzyme addition. Incubation was for 10 min at 42 °C in a final buffer concentration of 0.8 $\times$ H. To prevent nonspecific termination due to the low [ $\alpha$ -<sup>32</sup>P]TTP concentration, 1  $\mu$ l 0.5 mM TTP in 0.8 $\times$ H buffer was added after 10 min and incubation was continued for 10 min at 42 °C. The reaction mixtures were treated with 1  $\mu$ l 1 M NaOH at 100 °C for 3 min, chilled and neutralised with 1  $\mu$ l 1 M HCl. The DNA was finally precipitated with 150  $\mu$ l ethanol after addition of 0.5  $\mu$ g yeast tRNA (PL Biochemicals) in 45  $\mu$ l 2 M NH<sub>4</sub>OAc and washed twice with ethanol. Samples were dissolved in 90% formamide, 1 mM EDTA, 0.05% xylene cyanol bromophenol blue, heated to 100 °C for 3 min, rapidly chilled and loaded on the gel. Samples containing DNA templates were prepared in the same way omitting actinomycin D and the final NaOH treatment.

because of a strong stop signal in the RNA itself, the enzyme does transcribe right through the same sequence on the corresponding DNA template. This sequence can be read clearly to the A of the *Bam*I site at position -116 (Fig. 2c). Therefore, it is very likely that the end of the sequences derived from the mRNA template represents the 5'-end of the H2b mRNA. The *S. purpuratus* histone mRNAs are capped with the structure 7mGpppX<sup>m</sup>pYp (ref. 23). As we do not know if reverse transcriptase can copy the nucleotides at the X or Y positions of the 'cap' structure, we cannot conclude that G at position -71 is the very first base of the H2b mRNA.

The 5'-terminus of the H2b mRNA determined here maps next to a short nucleotide sequence which is common to all sequenced *S. purpuratus* histone genes<sup>3</sup>. This sequence, 5' PyCATTCPU 3' (boxed in Fig. 1), is found 50-70 bases upstream from the initiation codon for H2a, H2b, H3 and H4 and nowhere else in the sequenced part of the histone gene repeat unit. As the mature H2b mRNA does not contain this septanucleotide, it is probably not a translational control element. We note also that the 5'-end of the H4 mRNA has been tentatively located adjacent to the same sequence by matching H4 mRNA oligonucleotides to the known DNA sequence<sup>2</sup>.

If we assume that the H2b mRNA is 500 nucleotides long, we can predict the location of its 3'-terminus within the DNA sequence. Interestingly, this prediction locates the 3'-terminus next to a nucleotide sequence [5' CAXGAAAGAXT 3' (boxed in Fig. 1A)] which is common to all three histone genes (H2a, H2b and H3) which have been sequenced downstream from the protein termination codon<sup>3</sup>. The function of these sequences in histone gene expression remains to be determined.

We thank Dr M. Bina-Stein for communicating unpublished data, Dr J. Fiddes for technical advice, Dr J. W. Beard for reverse transcriptase. L.K. is an investigator of the Howard Hughes Medical Institute. The research has been supported by grants from the American Cancer Society, the NIH and the Veterans Administration.

**Note added in proof:** Recently we have formed DNA-RNA hybrids in the absence of formamide. This eliminated nonspecific chain termination events in sequencing the H2a, H3, H1 and H4 histone mRNA 5'-termini. Each of the 5'-termini coincides with the sequence 5'PyPyATTCPu3' in the genomic DNA.

# THE BARR & SROUD INTEGRATING MICRODENSITOMETER- DESIGNED TO REDUCE YOUR LABORATORY WORKLOAD

If you have a regular requirement for full quantitative cell information, it's worth checking out the Barr & Stroud GN5 Integrating Microdensitometer. With a scanning duration of only four seconds yet giving a 0.25 micron resolution, it brings speed and precision to cell preparation analysis.

The use of highest quality Leitz optics ensures reliability of results for even the smallest specimens. For histochemical and cytochemical studies, accuracy is better than  $\pm 1\%$  over an optical density range from less than 0.1 to greater than 2.5.

Area measurement, electronic masking and

narrowband illumination are just some of the other features which make this instrument a most attractive addition to your laboratory.

The GN5 Integrating Microdensitometer yields results with a speed and at a level of accuracy that far outstrips the standards that can be achieved by manual methods of study.

Designed in accordance with ergonomic principles, it's comfortable to work with too.

Start to reduce your laboratory workload by sending for full literature today. Use the journal reply system or, alternatively, contact us direct.

## Viroids and Viroid Diseases

by T.O. Diener, *US Department of Agriculture.*

A comprehensive, up-to-date account of the existing knowledge on viroids and the diseases they cause. It contains original ideas on the origin of viroids and novel hypotheses concerning their action in infected organisms. Since their discovery, viroids have created intense interest among many scientists because they are an entirely novel type of pathogen, constituting the smallest known agents of infectious disease; they cause a number of economically important plant diseases; they are nucleic acid molecules of unique structure not known before; they replicate and cause disease in spite of their small size and simple chemical composition, a fact considered impossible before their discovery; and they may have great implications in certain animal and human diseases. This book includes the most complete bibliography on viroids published to date.

## Mechanisms of Cell Change

edited by J.D. Ebert, *Marine Biological Laboratory, Woods Hole, Massachusetts*  
and T. Okada, *Kyoto University, Japan.*

An authoritative, timely, and concise volume focusing on the central problem of development, based on the essential mechanisms underlying the development of integrated multicellularity, diversified tissues, and organismic wholeness. It includes detailed coverage of recent Japanese discoveries, since Japan has emerged as one of the world's centres of research in the field. The book is based on the proceedings of the 8th International Congress of the International Society of Developmental Biologists.

508 pages  
(paper only) \$18.00/£9.00

## Diagnostic Electron Microscopy Vol. 2

edited by B.F. Trump and R.T. Jones, *both of the University of Maryland School of Medicine.*

This series offers the latest in technical and scientific information including discussion of laboratory management and the correlation of electron and light microscopy with standard techniques. Volume Two covers liver and bladder pathology, the hematopoietic system, ophthalmic pathology, gynaecology, peripheral nerve, and CNS disorders. Further volumes are in preparation.

April 1979

## Turtles: Perspectives and Research

edited by Marion Harless and H. Morlock.

A survey of all aspects of turtle biology ranging from care and management in research to conservation requirements and techniques. It examines current knowledge of turtles, including evolution, geography, biology and behaviour. Possibilities for future research are proposed and techniques are included for housing, handling, and treating turtles in research situations, CNS, sensory systems, and physiological data are summarized.

## Inbred and Genetically Defined Strains of Laboratory Animals Part 1: Mouse and Rat

edited by P.L. Altman and Dorothy D. Katz.

Inbred and genetically defined strains of laboratory animals are unique research tools: all members of an inbred line have essentially the same genetic constitution. An investigator is able, therefore, to restrict the biological variables affecting an experiment, and to repeat at other times or in other laboratories experiments requiring fine discrimination within a species. The profound insight that genetic expression gives to biological experiments has led to the rapidly increasing use of inbred and genetically defined animals. The difficulties in organizing the information for the different strains and species, and in developing a perspective on the number and availability of such animals, have presented a formidable barrier to those who are not primarily geneticists. The objective in preparing *Inbred And Genetically Defined Strains Of Laboratory Animals* was to organize and present the material in such a way that the range and nature of the data would be immediately accessible to those seeking the information for experimental purposes. Scientists requiring the mouse or rat in their research will find Part 1 of this new data book an essential reference source. Part 2 of this volume, covering hamster, guinea pig, rabbit, and chicken is in production. (*A FASEB Biological Handbook*)

## Viral Hepatitis

by R.S. Koff, *Veterans Administration Hospital and Boston University School of Medicine.*

A comprehensive data-base on the virology, immunology, epidemiology, and clinical features of acute viral hepatitis. The clinical spectrum of hepatitis virus infections, their differential diagnosis, and their management are emphasised. It will serve as a major reference source of detailed information on all aspects of viral hepatitis, which represents a major public health problem, and is an area in which there has recently been significant progress. (*A Clinical Gastroenterology Monograph*)

## Still the Queen of Sciences?

Nevill Mott

*Rutherford and Physics at the Turn of the Century*. Edited by M. Bunge and W. R. Shea. Pp. 192. (McGill University Press: Montreal, 1979.) \$20.

APART from Rutherford, this book reminds the reader of the many others who were around in experimental physics at the turn of the century. In Cambridge, of course, there was J. J. Thomson, in France Becquerel, the Curies and Jean Perrin, in Germany, Röntgen, Hertz, Boltzmann and Planck, and in Holland, Zeeman and Lorentz. These men, building on the great achievements in mechanics and electromagnetism of the nineteenth century, made the discoveries which set in train the developments which led to the second explosion in our understanding, that in the decade of 1925 to 1935. This book, centered on Rutherford, is about how physicists looked at themselves and their discipline at that time, and provokes a comparison between the situation then and that in the *annus mirabilis* of quantum mechanics, and also with the present time.

The book is a series of essays by physicists and historians given on the occasion of the Rutherford Symposium at McGill University in October 1977, though at least one essay (by the late Norman Feather) had been published previously. The first, by Erwin Hiebert of Harvard, describes the state of physics at the turn of the century. First, he writes about the self-image of the physicists. They were supremely confident and physics to them was the queen of the sciences. In the nineteenth century, heat and electricity, once the domain of chemistry, had been added to physics, then called 'natural philosophy'. Now the science of the atoms, the classical domain of chemistry, was being added too. Its prestige, according to the author, was because of its generality, fundamental nature and theoretical pertinence for all the other sciences. This might have been argued at any time, but it was advocated far more openly and brazenly than ever before. This was not because of the impact on the outside world; the future of electrical technology was seen to be very promising, but apart from this the applications of chemistry to industry,

Rutherford in 1905

agriculture and war were overwhelmingly more important, in contrast to the situation today.

Apart from Einstein's Special Relativity and Planck's introduction of a quantum of radiation, the period is represented as the heyday of the experimental physicists, unexpected phenomena like X-rays, the electron and the radioactive transformation emerging one after another from their work. In this it contrasts with previous periods, with the massive theoretical achievement of Maxwell and before him Newton, and with the period from 1924-30 which saw the formulation of quantum mechanics. In this period theoretical work was inspired by an idea that did not prove successful, namely that of the mechanical Ether, which it was felt might through some singularities account for the electron and for other particles.

The experimental approach is seen as particularly English. An interesting essay by Niel Cameron (McGill) says that French thinkers, notably Pierre Duhem and Henri Poincaré, "regarded English physicists with a mixture of admiration and exasperation. They could find in them no trace of their own drive to achieve elegance, symmetry, completeness—only a passion for workable hypotheses, mechanical models and demonstrations that could

be given a readily comprehensible meaning. From the French point of view, the English had *no* theory, in the grand sense of the word, only a kind of inspired thrashing about".

The reviewer wonders if this is still a feature of English physics, in contrast with that of other communities. With frequent exchange and emigration particularly to the US there is probably less difference between one advanced country and another, and representatives of different ways of thought are to be found everywhere. Nevertheless, he remembers vividly the day when some young research workers burst into his room in the Cavendish excitedly, "Prof, come and see a moving dislocation", and showed him the little dark lines darting about on the screen of an electron microscope. "Jolly little beggars", Rutherford would have called them, and this was in the typical tradition of our country.

Perhaps also this was the end of the era when it was possible to doubt the physical existence of atoms and molecules. Ostwald was converted by cloud chamber photographs; the scientific historian Ernst Mach, founder of the Vienna Circle, perhaps never; but on the whole Rutherford's materialistic view prevailed because of its success. Rutherford, according to an essay by Stanley J. Jaki (Seton Hall), spoke about that reality with an intense commitment "as if he were defending the honour of a woman he loved". On being told by Eddington that electrons possibly were only mental concepts and had no real existence, Rutherford exclaimed, "Not exist? Not exist? Why I can see them as plainly as I see that spoon in front of me".

Most of the classic Rutherford stories are to be found in this book; and for the reviewer, there are some new ones. Of particular interest is the account of his move to McGill and the reasons for it. McGill's physics building was splendidly equipped; the donor of the institute, William Macdonald, had spared no expense. Rutherford expected—as he wrote to his fiancée, Mary Newton, in 1898—to be "practically boss man in the laboratory", but in fact this took him some time to achieve. His predecessor was Callendar, the man who revolutionised thermo-

Photo: Otto Hahn

metry, who left behind him a strong research group to carry on this kind of work. Callendar was a pupil of J. J. Thomson, an athlete, a mathematician, physicist, classicist and a fellow of the Royal Society, the first of J.J.'s pupils to rise so high. In short, when Callendar left McGill his colleagues naturally doubted that anyone so fine could be found to replace him. So at the end of his first year in McGill, Rutherford wrote to Mary Newton still waiting for him in New Zealand, "I am getting rather tired of people telling me how great a man Callendar was, but I always have the sense to agree. As a matter of fact, I don't quite class myself in the same order as Callendar, who was more an engineering type than a physicist, and who took more pride in making a piece of apparatus than in discovering a scientific truth". "This expression of snobbery"—as one essay puts it—"makes clear enough where Rutherford stood on the relative merits of pure and applied research".

And, as all the world knows, he had his way in McGill and achieved supreme success there (and incidentally the Nobel Prize for chemistry). Two things he had learned at the Cavendish had helped him. One was that one need not strive for accuracy in pioneering work. "In measuring the mechanical equivalent of heat (as did Callendar), "infinite pains are required"; in chronicling the activities of his "jolly little beggars" (ions), two-place accuracy would normally suffice. And the other was—how to form a research group. In fact, an interesting article by Lawrence Badach maintains that at McGill, Rutherford "laid the foundations of big science" in ways we would now take for granted, but perhaps not then: by the publicity he gave to his work, by the flow of research reports and publications in *Nature* and the *Philosophical Magazine*, and by the formation of research groups. Nothing succeeds like success, and it is perhaps true that at McGill Rutherford set the pattern which has carried physics to its present heights.

On reading this book, I am tempted to contrast the physics community of 1900 ( $\pm 5$ ) with the Cavendish I first knew from 1927-33, and with the situation today. In 1902 one is almost surprised to find Rutherford writing to his mother from McGill, "I have to keep going, as there are always people on my track. I have to publish my work as rapidly as possible in order to keep in the race". This feature surely remains. In 1930, as now, all over the world in all branches of science there were and are enthusiastic research groups, enjoying their work, eager to publish and to stay in the race.

But there are now many more races. Rutherford's beloved nucleus, alas, can only be pursued with megabuck machines and a degree of theoretical understanding that eludes most scientists, even physicists in other specialities. Even a branch of the subject like solid-state physics has split into many divisions: semiconductors, metals, mechanical strength, plastics and amorphous materials, each with its journals and international conferences. In contrast to 1900 and 1930, the technological importance of physics, especially in microcircuits and nuclear energy, is enormous. The computer, a child of physics, enables the behaviour of matter to be predicted in a way that would have been inconceivable

two decades ago. Whether physics is still "Queen of the Sciences" as in 1900 and 1930 is more doubtful; some of the most startling developments in the last decades have been in biology, both pure and applied. However, most physicists will feel, rightly or wrongly, that an understanding of nature is only complete when expressed in the language of physics, and in that sense now as then we can believe that ours is the supreme discipline. □

*Sir Nevill Mott was until 1971 Cavendish Professor of Physics at Cambridge. For his research work on the application of quantum mechanics to problems of solid-state physics, including non-crystalline semiconductors, he was awarded the Nobel Prize for physics in 1977.*

## What everyone needs to know about cancer immunology

*Handbook of Cancer Immunology.* Vol. 1: Basic Cancer-Related Immunology. Vol. 2: Cellular Escape from Immune Destruction. Vol. 3: Immune Status in Cancer Treatment and Prognosis (Part A). Vol. 4: Immune Status in Cancer Treatment and Prognosis (Part B). Vol. 5: Immunotherapy. Edited by H. Walters. Pp. 1867. (Garland: New York and London, 1979.) \$37.50 each volume; \$165 the set.

SOME 25 years ago it became accepted that experimental animal tumours expressed neoantigens which elicited immune responses in the autochthonous host, or as its nearest approximation syngeneic hosts receiving transplanted tumour, and these responses could control tumour growth. Since then there has been an enormous growth of research into many aspects of the immunological recognition of malignant cells. Today this approach to cancer is at a stage where there is a need to review the concepts developed over the past years, rejecting those which no longer seem tenable and consolidating those deemed worthy of further study. Indeed critics will say the time has come for tumour immunology to substantiate the concept that host immune responses really do play a significant role in controlling cancer development.

Against this background, these five volumes attempt to provide an overview of basic developments in cancer immunology. This begins (volume 1) with a series of chapters on basic cancer immunobiology, and volume 2 deals exclusively with mechanisms by which tumours may escape immune destruction. Many of the individual

articles are excellent, providing short informative reviews of topics of particular interest to the authors. Nevertheless, one is left to draw one's own conclusions about the basic concepts of tumour immunology. For example, one would have expected volume 1 to provide a critical assessment of the relative merits of chemically-induced and virus-induced tumours compared with naturally arising animal tumours as models for human cancer. In fact this problem is not considered until later (volume 3) in reviewing the role of macrophages in resistance to cancer. The mechanisms by which tumours may escape immune destruction are considered in some considerable detail (volume 2) and this topic is further reviewed in volume 4. Altogether these articles provide a comprehensive survey of humoral factors such as circulating tumour antigen and antigen-antibody complexes which may interfere with cell-mediated immunity to tumour cells. But what of suppressor cells and factors released by these cells? Apart from their consideration in one particular animal system, there is no clear statement of opinions as to whether these cells do or do not play a decisive role in modulating immunity in tumour-bearing animals.

Turning next to human cancer, volumes 3 and 4 contain a series of articles presenting studies on specific types of malignant disease. The objective here is to review evidence that the selected human cancers do elicit immune responses in the patient. Here the selection of human tumour types for review and the order of presentation is somewhat puzzling. In reviewing studies with solid tumours and leukaemias the critical evaluation of methods for detecting cell-mediated and humoral immune responses is presented in volume 4, but this is preceded in volume 3 with chapters dealing with specific examples such as malignant melanoma and cancer of the

## Health and the Family

edited by C. Wood

June/July 1979, xiv + 240pp., £11.60/\$24.50 0.12.8089.118505 (Published jointly with Grune and Stratton)

This volume deals in an unusually comprehensive way with one of the major human problems of this century, the changing status of the family. A wide range of experts from the United States and Britain consider this problem, its causes and its effect. It is important for the health professions and in particular the physician to understand the nature of this change and the importance of adapting medical education to the problems that arise. Each chapter deals with a specific aspect of the problem including the family-orientated birth, the feminist and birth-control movements, attitudes towards the aged and the effect of television on the young as well as new developments in medical education. Chapters on new educational developments in family medicine, internal medicine, paediatrics, obstetrics and psychiatry all describe the growth of a more human and personalised approach to health problems of the individual and the family. The final chapters call upon health professionals to deal more effectively with the modern epidemics of mental ill-health, alcoholism and drug abuse as well as to provide for the health needs of an increasingly aged population. This book brings together issues and problems relating health care and medical education with the sociology of the family, and illustrates the importance and unique relationship between them.

## Fantasy and Symbol

Studies in Anthropological Interpretation

edited by R. H. Hook

July 1979, xii + 304pp., £11.80/\$25.00 0.12.351250.6

Fantasy and symbol have played a part in art and life since the beginning of civilisation itself. This outstanding collection of essays in honour of George Devereux comprises papers originally presented at a symposium on 'Psychoanalysis and the Interpretation of Symbolic Behaviour' at Canberra in 1975, augmented by a number of provocative and scholarly essays by other distinguished and world-famous anthropologists on the theme of symbolic interpretation in anthropology. The collection starts with a paper by Devereux himself, arguing that fantasy and symbol, often thought to be concerned only with an unreal or imaginary world, in fact play an important part in the actions and events of daily life. Claude Lévi-Strauss examines the place taken by seeds of the bean in the myths and rites of peoples of the Ancient, Old and the New World, in an original and entertaining essay. Subsequent papers deal with symbol and fantasy in ritual and myth. This book will be of great value to anthropologists, those interested in transcultural and comparative psychology, psychiatry and psychoanalysis, or those concerned with the interpretation of myth and ritual.

Proceedings of the Serozo Symposia: No. 23

## Somatomedins and Growth

edited by G. Giordano, J. J. Van Wyk and F. Minuto

July 1979, c. 362pp., £17.60/\$37.00 0.12.285350.4

This book summarises the original papers and discussions presented at the International Symposium on Somatomedins and Growth, held at Santa Margherita, Italy, in March 1978. This symposium provided the opportunity for investigators from many different disciplines to summarise and integrate the vast amount of data which is now emerging from laboratories around the world on the chemistry and physiology of the somatomedin family of peptides. Papers were presented on the nature of somatomedins in blood, methods for their detection and the origins and physiological significance of the somatomedins. Particular emphasis was placed on the chemical nature of these compounds and their unique binding properties. Consideration was also given to the comparison of results obtained by radioreceptor assay, protein binding assay and radioimmunoassay, and to the effect of administering somatomedins to experimental animals. This book contains much that will be of interest to endocrinologists, in particular pediatric endocrinologists and diabetologists. It will also be of value to cell biologists concerned with nutritional and hormonal factors involved in cell growth.

## Speech-Hearing Tests and the Spoken Language of Hearing-Impaired Children

edited by J. Bench and J. M. Bamford

Summer 1979, xviii + 528pp., £23.50/\$45.00 0.12.088450.X

Speech-audiometry has an established place in the group of tests used by audiologists, speech and hearing therapists, educational audiologists and teachers of the deaf in order to assess a person's hearing for speech. Most speech audiometry is conducted with word lists, but some make use of lists of sentences. Until now, existing tests consisting of sentence material have been of questionable validity for testing children's speech-hearing ability. In particular, tests have been linguistically too advanced, especially with regard to the complexity of their grammar and vocabulary. This book reports the results of a large scale research project in which the primary aim was to overcome this difficulty by designing new and more appropriate speech-audiometric tests for hearing-impaired children aged 8-15 years. The background to and procedure for the research is described and discussed in detail, and the final speech tests themselves (the Bamford-Kowal-Bench (BKB) Sentence Lists for Children) are presented. The reader is given ample information on the reliability and other practical aspects of the new tests.

## Advances in Marine Biology: Volume 16

edited by F. S. Russel and M. Yonge

June 1979, xii + 436pp., £32.50/\$68.50 0.12.026116.2

Volume 16 opens with a review by R. V. Gotto of our knowledge of the systematics, occurrence, and habits of copepods living in association with marine invertebrates, many of whose actual relationships with their hosts is as yet little known. G. A. Paffenhöfer and R. P. Harris discuss the laboratory culture of wholly planktonic animals as a contribution to the understanding of food webs in the sea. The second article by A. J. Underwood reviews the ecology of intertidal gastropod molluscs from the points of view of the factors limiting their distribution and the causes of spatial and temporal variations in their abundance. Finally G. Y. Kennedy contributes an article on pigments in marine invertebrates. Marine animals and plants are often brilliantly coloured and a knowledge of the chemical composition of these pigments throws light on their evolution and physiological significance. This volume maintains the high standard of the series. With its detailed, authoritative reviews it will be of interest to fish biologists, oceanographers and biologists in general.

## Coal and Modern Coal Processing

edited by G. J. Pitt and G. R. Millward

July/August 1979, xii + c. 220pp., £8.50/\$18.00 0.12.557850.4

With the predicted exhaustion of oil reserves within decades, the importance of coal as a source of energy and chemical feedstocks is increasing rapidly. The need to develop means of processing coal more efficiently has been accompanied by the involvement of increasing numbers of scientists and engineers in research and development work on new coal processes. The purpose of this book is to provide a succinct and up-to-date introductory account of the formation, structure and main properties of coal, with brief descriptions of processes for converting it into gas, liquid fuels, coke and graphite, and for its combustion for heating and power generation. Some of the chapters include accounts of recent work that have not been published elsewhere, and sources of more detailed information are indicated throughout. It will be particularly suitable for graduates, technical staff and undergraduates in fuel science and chemical engineering, and for all those entering the coal processing industry.

## Cold Tolerant Microbes in Spoilage and the Environment

edited by A. D. Russel and R. Fuller

June/July 1979, xii + 164pp., £9.80/\$21.00 0.12.603750.7

This volume, Number 13 in the *Society for Applied Bacteriology Technical Series*, originated at a Demonstration Meeting of the society held at Brunel University's Department of Biology in Autumn 1977. The subject of the meeting was one of increasing importance to microbiologists: "*Cold Tolerant Microbes in Spoilage and the Environment*." Contributions have been brought together from experts on psychrotrophic bacteria to show their various effects on fundamental metabolism, ecology and food spoilage in the context of low temperature microbiology. An excellent survey is thus provided of the importance of psychrotrophic bacteria and of techniques involving psychrotolerant and psychrotrophic micro-organisms. For those involved in this particular area of microbiology, notably food and dairy scientists, a reference work of this standard will prove to be essential reading. It will also be of particular value to bacteriologists, cryobiologists and microbiologists, and to postgraduate and undergraduate students in these areas.

## Non-Metallic Solids: A Series of Monographs No. 1

edited by J. P. Roberts and P. Popper

## Glass Ceramics Second Edition

P. W. McMillan

July/August 1979, viii + 284pp., £16.60/\$35.00 0.12.485660.8

Since the first and widely acclaimed edition of 'Glass-ceramics' was published in 1964, the theoretical and commercial bases of this industrial science have been transformed. This second edition, greatly revised and enlarged, describes both the theoretical and practical aspects of glass-ceramics and presents a distillation of previously unpublished ideas and data. Its discussion, for example, of the formation of glass-ceramic microstructure and of microstructure-property relationships covers completely new ground. Important recent developments are surveyed, including processes for the production of very high strength materials and machinable glass-ceramics. The discussion of the applications of glass-ceramics ranges from considerations of fields in which the materials are firmly established to areas where the potential of the materials still awaits full exploitation, such as uses in nuclear power engineering and in the medical field. Throughout the text, where processes are discussed, they are illustrated by practical examples.

## The Earth: Its Origin, Structure and Evolution

edited by M. W. McElhinny

July 1979, xiv + 598pp., £36.00/\$74.50 0.12.482750.0

In this important research volume, faculty members of one of the leading research institutes in geochemistry and geophysics present reviews of the current state of knowledge of various aspects of the origins and composition of the Earth. The book begins by discussing the origins of the Earth, and goes on to consider its composition and structure, from core to crust, as deduced from seismology, geomagnetism and laboratory studies of phase transitions and physical properties at high temperatures and pressures. Geochemical aspects of the evolution of the upper mantle and crust are also discussed, including the origin of magmas, porphyry copper deposits, the isotopic evolution of granite and the distribution of rare earth elements in the continental crust. The final chapters review palaeomagnetic studies related to the past distribution of continental crust, with discussions of the geomagnetic polarity time scale and of continental drift since the Devonian. This book will be of great interest to anyone needing a review of particular aspects of the origin, structure and evolution of the Earth: students and researchers in the earth sciences, geology, geophysics and geochemistry.

## Biology and Systematics of Colonial Organisms

edited by G. Larwood and B. R. Rosen

June 1979, x + 588pp., £40.00/\$82.75 0.12.436960.X

Coloniality is a very loosely used word in biology and if it is used precisely it generally has different meanings for different specialists. A very wide range of organisms are supposed to show colonial or social behaviour, including bacteria, protozoans, coelenterates, bryozoans, echinoderms, bivalves, certain insects and gregarious vertebrates including man. Is there a common factor to these different biological associations or are there very different biological phenomena involved? In this volume specialist authors from a wide range of research backgrounds present their views on a particular group of colonial or social organisms. The editors have tried to cover as many different groups as possible, fossil and living, but inevitably the bias is on invertebrates. There is a general emphasis throughout on the likely adaptive advantages and possible evolutionary reasons for the development of coloniality. Within this general framework subjects discussed include coordination, histoincompatibility, functional morphology, chemoreception, electrophysiology and the ecological strategies of colonial growth forms.

# Numerical Analysis of Singular Perturbation Problems

edited by P. W. Hemker and J. J. H. Miller

June/July 1979, xii + 500pp., £17.50/\$37.00 0.12.340250.6

The analytical theory of singular perturbation problems is a well established area of research, which has been developing for many years. On the other hand, the numerical analysis of such problems seems to have received relatively little attention and most of this has been in the last few years. As a result of this rapid expansion of interest in recent years a conference was organised at the Catholic University, Nijmegen, The Netherlands from 30 May to 2 June 1978, to bring together mathematicians working on these problems. These published proceedings contain a collection of new explorations in the field and several applications. This volume will be of interest to research workers and lecturers in applied mathematics and numerical analysis and to all those concerned with the application of numerical methods to singularly perturbed problems such as boundary layer problems.

## The Physics of Laser Fusion

H. Motz

June/July 1979, x + 290pp., £17.50/\$37.00 0.12.509350.0.

This book provides the first synthesis of the physics of laser fusion to be accessible to the wide audience of physicists and engineers who are interested in the field but not necessarily specialists. Laser compression of matter for fusion reactions is one of the most promising approaches to the resolution of the energy problem, and research towards this end is rapidly progressing in several countries, drawing on many branches of physics. Since few specialists even can be well acquainted with each of these branches the book provides the background theory in each one and draws the various strands together to show their applications to the laser fusion problem.

## Analytical Chemistry

Second Edition

D. J. Pietrzyk and C. W. Frank

March 1979, xx + 700pp., £10.70/\$16.50 0.12.555160.6

The extensively revised version of this important textbook has a dual objective: first, to acquaint students with the fundamental principles encountered in modern chemical and instrumental methods of analysis; secondly, to enable students to master the basic quantitative skills and techniques required to perform careful measurements in the laboratory. In order to broaden the scope of the book, the authors have repeatedly used examples from related disciplines to illustrate the fundamental principles.

## Behavioural and Neural Biology

edited by J. L. McGaugh

Publication, Monthly. Subscription, Volumes 25-27, 1979 £112.00/\$185.25 \$157.50 (USA)

*Behavioural and Neural Biology* publishes major theoretical and review papers, experimental papers and brief communications of research findings, in all areas of neurobiology and behaviour. As an interdisciplinary journal, it includes papers concerned with neuro-anatomical, neurophysiological, neurochemical, neuropharmacological and neuroendocrinological bases of behaviour, as well as papers dealing with human and infrahuman behaviour from a biological perspective, including studies of behaviour genetics and field studies. Prompt reviewing and publishing ensure that the material is as up-to-date as possible.

## Journal of Applied Biochemistry

edited by J. J. Marshall

Publication, Bimonthly. Subscription, Volume 1, 1979 £27.30/\$45.00 \$45.00 (USA)

*Journal of Applied Biochemistry* is a new international journal devoted to the publication of papers presenting original results, review articles and other features in the field of applied biochemistry. Results of fundamental studies directly related to the design of new biotechnology, the improvement of existing biochemical processes, and the preparation, utilization, conversion or application of biological materials will also be published.

Published for the International Union of Biochemistry

Prices include Postage.

## Editorial Policy

- The primary aim of CELL CALCIUM will be to publish high-quality articles quickly and efficiently and thereby become the principle interdisciplinary forum for research on calcium
- Articles from all branches of science and medicine will focus on cell calcium homeostasis and the regulation of cell function by calcium
- Original research papers will dominate the contents but reviews and hypotheses will be accepted. Comments on published articles and items of information to the "Calcium Community" (e.g. conference announcements and reports) will also be published
- To ensure rapid publication, CELL CALCIUM will appear monthly and printing will be directly from typescripts prepared by the author
- The first issue is scheduled for January 1980. You are invited to submit articles to the editor

CELL CALCIUM will appear monthly; 6 issues per volume; US\$90 (£45) per year (inclusive of postage)

# Churchill Livingstone

brain and bladder. Nevertheless, these chapters present accounts of the current status of research into the immunology of human cancer and it is refreshing to read critical appraisals in which the concepts developed from experimental animal tumour studies are tested. This includes an evaluation of the *in vitro* techniques for measuring cell-mediated immunity to human tumours, the conclusion being that these are not satisfactory for detecting or monitoring immune reactivity in cancer patients. Several of the chapters in volumes 3 and 4 also consider techniques for detecting antibody responses to human tumours. This approach came into vogue in the late 1960s, but with the introduction of more sophisticated assays which were thought to detect sensitised lymphocytes it fell out of fashion. Following recognition that the cell-mediated assays are more complex than originally thought, there has been a resurgence of interest in testing for anti-tumour antibodies. In this context it is recognised that antibody assays are particularly applicable for monitoring the isolation of tumour antigens in subcellular fractions. Unfortunately the biochemistry of tumour antigens is not dealt with in any great detail in these volumes, although the potential of the serological approaches in defining tumour antigens is illustrated in a review of melanoma associated antigens.

The final volume of the series sets out to review approaches for the immunological treatment of cancer. Surprisingly a variety of non-specific

agents such as cyclic nucleotides, polianions, levamisole and neuraminidase are considered, whereas the 'well-tried' agents, BCG and C parvum, receive little attention. This approach may have been deliberate, as there are numerous reviews on cancer treatment with bacterial adjuvants. Nevertheless, this is to be regretted, as most of the clinical trials being carried out around the world have used either BCG or C parvum and so a critical appraisal of this work should have been presented as a basis for the 'newer' approaches. This volume clearly emphasises how little is known of the inter-relationships of cell-mediated and humoral immune responses generated by a developing tumour so that it is still essentially impossible to devise rational approaches to the immunological treatment of cancer.

This is an ambitious series of volumes which probably succeeds as well as could be expected considering the vagaries of the individual contributors. The series as a whole provides an overview of cancer immunology but never really comes to grip with the basic problems. These concepts could have been presented in a much more economic fashion, which would have been more appealing to the uninitiated seeking guidance into the vast literature on cancer immunology.

R. W. Baldwin is Professor in Tumour Biology at the University of Nottingham, and Director of the Cancer Research Campaign Laboratories, Nottingham, UK.

## Virus diseases of trees and shrubs

*Virus Diseases of Trees and Shrubs.* By J. I. Cooper. Pp. 74. (Institute of Terrestrial Ecology/National Environment Research Council: London, 1979.) £3.

THIS book is a comprehensive collation and review of the virus, virus-like and mycoplasma diseases of a wide range of the exotic and indigenous trees and shrubs found in Britain. The book does not cover *Malus*, *Prunus* and *Pyrus* species because the author felt that these plants had been adequately covered in the literature on the virus diseases of fruit trees.

Many of the virus diseases discussed were studied in other countries but they are likely to occur or be introduced into the UK. Dr Cooper also describes the main methods of studying these diseases and determining their means of spread, deleterious effects and methods of control.

It is only in recent years that this important group of diseases of trees and shrubs has been studied. This book is a very useful summation of the available information, although there are a few conspicuous omissions, for example, virus diseases of *Chaenomeles*, *Cladrastis* and *Hibiscus* species. The book is clearly written and presented, and very well illustrated with a total of 65 colour and monochrome photographs, providing a very useful identification and reference guide to those involved in the study and diagnosis of tree and shrub diseases, or those involved in the propagation and production of woody plants. At the very reasonable price of £3, it is well within the reach of students and educational establishments and will do much to make horticulturalists, plant pathologists and plant health inspectors aware of the previously neglected, but important subject of the virus diseases of trees and shrubs.

## Biology of the intertidal zone

*Biology of Intertidal Animals.* By R. C. Newell. Third edition. Pp. 781. (Marine Ecological Surveys: Faversham, UK, 1979.) £22.

It is almost ten years since the first edition of Professor Newell's book appeared, and during those ten years there has been a revolution in the approach to the study of intertidal animals. Much of the natural history, the ways of life and overall ecology of the commoner intertidal animals was familiar and ably put together in the first edition. What has happened since is a reappraisal of intertidal invertebrate biology by zoologists interested in the physiological and biochemical strategies used by animals in adaptation to their particular niches. Fields of particular interest which may be mentioned are those of temperature acclimation, energy budgets and facultative anaerobiosis. This new edition contains much of the original descriptions of the basic natural history, feeding mechanisms, and so on. Although these parts are brought up to date, the arrangement of the chapters is different and reflects this change in emphasis which has occurred within the last few years.

The book is cast in four sections: distribution patterns, energy acquisition, metabolic energy expenditure, and a final chapter on energy budgets. Thus, although the first edition ended with a chapter on thermal stress and desiccation, the tolerance of environmental stresses generally is brought forward and the subject is properly discussed after the initial descriptions of the intertidal environment. This includes the recent work by Trueman and coworkers on burrowing. The descriptions of faunas of special habitats has been updated by the inclusion of the discussion of the work of Fenchel, Wieser and others on the role of bacteria and other microorganisms in the ecology of fine deposits. The chapter which follows integrates the many diverse factors influencing the distribution of intertidal organisms, emphasising the fact that the distribution and occurrence of any species is the resultant of the interplay of many factors. There is a useful introduction to Alderdice's approach to this problem illustrated by various examples, including Professor Newell's own recent work on *Ligia*. In the energy acquisition section there are useful discussions of the roles of dissolved nutrients, of microorganisms in the energy equations, and of deposit and filter feeding, and it is indicative

of the modern approach that these discussions precede the description of the actual feeding mechanisms. The concept of ration and factors affecting feeding rate and the energy budgets are properly discussed after the updated descriptions of feeding.

The third section concerns energy expenditure indicated by respiratory rate and includes discussions of the interesting work of de Zwaan, Bayne, Hockachka and others on facultative anaerobiosis and of the factors affecting the rate of oxygen uptake in aerobic conditions. The final chapter attempts an integration of the various adjustments available to organisms to maintain optimal fitness.

Review papers and some recent books concerned with thermal acclimation, anaerobic pathways, enzyme biochemistry and multi-factorial analy-

sis are not easy reading even for most advanced undergraduates. Where Professor Newell deserves congratulation in his new edition is in not only providing excellent summaries in themselves but in giving sufficient background for students for an appreciation of these exciting fields of research as an introduction for their further study. The book is very well produced in a larger format than the original and is to be recommended to all who wish to understand the biology of the intertidal zone. No library serving students' needs in the biological sciences should be without it.

R. P. Dales

R. P. Dales is Professor of Zoology at Bedford College, University of London, UK.

## Rock mechanics

*Experimental Rock Deformation: The Brittle Field.* By M. S. Paterson. Pp. 254. (Springer: Berlin, Heidelberg and New York, 1978.) DM48; \$24.

LABORATORY experiments aimed at defining the mechanical characteristics of rocks under high confining pressure constitute a growth industry; people concerned with tectonic processes, earthquakes or the proper design of foundations for civil engineering projects are the customers. The subject divides naturally into the study of plastic deformation and the study of brittle fracture: the monograph under review is largely concerned with the second, but in spite of its title, it incorporates a valuable chapter on the brittle-ductile transition in rocks.

Professor Paterson, who has built up a flourishing school of rock mechanics in Canberra, has successfully set out to assemble a concise source-book. The bibliography is very extensive indeed and a scan through dates shows how modern a subject this is. David Griggs in California, building on the experimental genius of Percy Bridgman, was the father of modern rock mechanics, and his first citation dates back only to 1935. This bibliography will be of lasting value.

There are major differences between the mechanical behaviour of rocks and of metals, even brittle metals. Professor Paterson shows an impressive familiarity with the metallurgical literature and refers to it whenever it can illuminate a matter in hand; a special appendix is devoted to modern fracture mechanics, the metallurgists' creation. One special feature of rock behaviour

which is very clearly set out here is the linkage between incipient fracture and an anomalous enhanced dilatancy, an increase in specific volume. In the brittle-ductile transition, dilatancy again plays a major diagnostic role, and a distinction can be made between *cataclastic* flow (the microfracturing of rock followed by relative displacement of the fragments) and true crystal plasticity. The former process, but not the latter, is associated with measurable dilatancy. It seems that the dilatancy here discussed is much larger than the uniaxial microstrain preceding yield long studied by metallurgists.

Another unfamiliar subject well explained in the book is the stick-slip mechanism of frictional displacement, which has numerous implications for the behaviour of rock, both macroscopic and microscopic; presumably it serves to define the conditions of cataclastic flow. This chapter nicely supplements the long familiar treatment by Bowden and Tabor (*The Friction and Lubrication of Solids*; Clarendon/Oxford University Press: Oxford, 1950, 1964), who largely concern themselves with metallic friction. In this chapter and elsewhere in the book, Professor Paterson shows a necessary concern with the characteristics of the testing machine, stiffness in particular, which have a marked effect on the apparent fracture or flow behaviour of rock samples.

The book is exceptionally good value for money, and the reviewer now looks forward to completing his set in a few years' time with a companion volume on the plastic deformation of rocks.

R. W. Cahn

R. W. Cahn is Professor of Materials Science at the University of Sussex, Brighton, UK.

# ANNOUNCING A MAJOR NEW JOURNAL THYMUS

the international  
journal of thymology

This journal has been created to meet the increasing demand for comprehensive and integrated coverage of progress in all areas related to the thymus. A strict editorial policy will ensure that only those papers reflecting and contributing to advances currently taking place will be considered for inclusion. Providing a unique forum for researchers and clinicians, the journal should stimulate the constructive

exchange of ideas and advances between immunologists and endocrinologists in this field.

## Aims and Scope

This journal is devoted to the publication of material within the general field of Thymology. Contributions on both clinical and basic developments of immunobiology in relation to the Thymus in its broadest sense will be considered for publication. This will include studies related to T-lymphocytes and immunodeficiencies as well as pathological and biochemical studies.

## APPOINTMENTS VACANT

### UNIVERSITY OF NATAL

#### DEPARTMENT OF BOTANY PIETERMARITZBURG

Applications are invited from suitably qualified persons regardless of sex, religion, race, colour or national origin, for appointment to the post of

#### LECTURER

Preference will be given to candidates who have a particular interest in the field of the higher cryptogams but who would also be willing to assist in the teaching of flowering plant taxonomy and/or phytogeography.

The successful applicant will be expected to participate in the normal teaching of undergraduate courses, including field excursions, and to engage and supervise research in one of the above fields of botany.

The salary will be in the range: R8,100 to R13,200 per annum.

The commencing salary will be dependent on the qualifications and/or experience of the successful applicant. In addition, an annual vacation savings bonus is payable, subject to Treasury regulations.

Application forms, further particulars of the post and information on pension, medical aid, group insurance, staff bursary, housing loan and subsidy schemes, long leave conditions and travelling expenses on first appointment are obtainable from the Registrar, University of Natal, P.O. Box 375, Pietermaritzburg, 3200, South Africa, with whom applications, on the prescribed form, must be lodged not later than August 31, 1979, quoting reference PMB 33/79.

W179(A)

### UNIVERSITY OF CAMBRIDGE

#### PATHOLOGY DEPARTMENT POSTDOCTORAL RESEARCH BIOCHEMIST

Applications are invited from biochemists with some postdoctoral experience to fill an M.R.C. funded postdoctoral research assistantship, to collaborate on various aspects of collagen biosynthesis by cultured cells. This would involve setting up known assays for various post-translational enzymes, as well as collagen purification, chain separation and characterisation.

The appointment is for a period of 2 years in the first instance with an initial salary of £4,631 per annum, on Range 1A of the University Scale and of £4,882 for the second year.

Applications, as well as requests for further information, should be sent to Dr C. I. Levene, Department of Pathology, University of Cambridge, Tennis Court Road, Cambridge CB2 1QP; they should include a brief curriculum vitae, and names and addresses of 2 referees. It is hoped to fill the post by early August, 1979, or as soon as possible thereafter.

2249(A)

### PRESTON POLYTECHNIC

Applications are invited  
for the post of

#### LECTURER II IN BIOLOGY

Preference will be given to applicants with qualifications and experience in cell physiology, animal physiology or medical laboratory science.

Salary scale (under review): £4,101 to £6,558.

Application forms and further particulars may be obtained from the Personnel Officer, Preston Polytechnic, Corporation Street, Preston PR1 2TQ, to whom completed applications should be returned within 14 days from the appearance of this advertisement.

2198(A)

### SOUTHAMPTON GENERAL HOSPITAL DEPARTMENT OF HISTOPATHOLOGY MEDICAL LABORATORY SCIENTIFIC OFFICER OR JUNIOR B

The post is suitable for persons studying for H.N.C. or the special examination of the I.M.L.S. The work covers a wide range of techniques undertaken in well-equipped laboratories and there is close liaison with the Departments of Neuropathology, Electron Microscopy and University Experimental Pathology.

Further information from Senior Chief Medical Laboratory Scientific Officer, Miss M. Litchfield, telephone Southamton 777222, ext. 3956. Application forms from Mr F. Finner, Personnel Department, Southamton General Hospital, Telephone Southamton 777222, ext. 4100.

2200(A)

### SENIOR EDITOR

The International Schools Division of Macmillan Education Limited need an experienced Senior Editor to take charge of and develop a section of their schools publishing programme overseas, particularly but not exclusively in West Africa.

The job will involve commissioning parts of the list and being responsible for other editors who also commission.

The successful applicant will

- be imaginative and resourceful
- be profit conscious
- have a knowledge of overseas markets
- preferably have a science degree

Please apply with full c.v. to:

M. J. Thorowgood, Publishing Director, Macmillan Education Limited, Houndmills Industrial Estate, Houndmills, Basingstoke, 2234(A)

## DEVELOPMENT BIOCHEMIST

### BRIDGEND SOUTH WALES

### SALARY £ NEGOTIABLE

Miles Laboratories Ltd are market leaders in the manufacture of diagnostic and pharmaceutical products. The manufacturing division is situated at Bridgend where they produce for the Home and Export markets. This is a new post in the Product Development Department and offers a good opportunity to join a reputable progressive company.

Reporting to the Senior Allergen Development Chemist you will take responsibility for specific projects which will include characterisation of allergen products, definition of the processing conditions, purification and a variety of work connected with allergen development.

Ideally we are seeking someone in their mid-twenties experienced beyond first degree level or completing post graduate work. Your experience should be in protein or enzyme chemistry involving a range of biochemical techniques. A knowledge of immunological applications would be advantageous in this specialised area of development. Working conditions are very pleasant and in addition to an excellent negotiable starting salary, relocation expenses to this most attractive area are available.

For further information please phone Pamela David on

# Mathematician/Physicist (or Meteorologist)

## ENVIRONMENTAL PHYSICS RESEARCH

The Environmental Physics Section, whose role at CERL is to study the physical, meteorological, and mathematical aspects of the dispersion and fate of pollution in the atmosphere, requires a mathematics or physics graduate, preferably with post-graduate experience, to undertake theoretical research on the effects of power station emissions upon climate. Of particular interest is the effect upon atmospheric temperature of carbon dioxide produced by fuel burning on a global scale and the eventual fate of this carbon dioxide in the atmosphere-ocean-biosphere system.

It is proposed to carry out this work in parallel with current research on the effect of air pollution on crops, the transport and deposition of pollution in rain and snow over large distances, and the analysis of meteorological and chemical data from long range aircraft flights. The successful candidate would be encouraged to interact with these projects whilst developing an informed position on all aspects of the carbon partitioning problem.

He/she would be working within a group of theoretical and experimental scientists studying a range of pollution problems. Excellent small and large computing facilities are available together with the latest mobile remote sensing equipment and meteorological instrumentation.

Candidates should have good honours degrees in mathematics or physics. Post-graduate study or employment experience in meteorology, fluid mechanics, or the environmental sciences would be an advantage, but we would also be interested to hear from more recently qualified graduates with an interest in entering the field.

The Laboratories are situated in a pleasant part of Surrey and offer attractive conditions of service, and facilities for the total of 800 Research and Support Staff engaged in a broad spectrum of research into the materials, technologies, and plant performance problems of the Central Electricity Generating Board.

**The initial appointment will be made within the salary range of £4300 to £7900. There are internal career prospects for advancement to research ranges of up to £10,700 and most higher graded management positions are also filled from within. These salary ranges are currently under review.**

Application forms are obtainable from the Head of Personnel Development & Services Section, Central Electricity Research Laboratories, Kelvin Avenue, Leatherhead, Surrey KT22 7SE or telephone Leatherhead 74488 Ext 363, quoting reference number **RL/5/DT**. Closing date is: **Friday 6 July 1979**. 2266(A)

## CENTRAL ELECTRICITY RESEARCH LABORATORIES

### THE UNIVERSITY OF LEEDS

#### FOOD SCIENCE DEPARTMENT

#### FOOD SCIENTIST

A FOOD SCIENTIST is required to work in the Catering Research Unit of the above Department. The work, which is supported by the Department of Health and Social Security, is connected with the application of the techniques of food science and technology to the large-scale feeding industry. Applicants should have a degree in Food Science/Technology or in a related field. The appointment will be for a fixed term ending on September 30, 1980.

Starting salary at an appropriate point on the 1B or 1A scale for Research and Analogous Staff (£3,689 to £7,145 per annum, under review).

Further information can be obtained from Mr G. Glew, Catering Research Unit, Food Science Department, The University, Leeds LS2 9JT.

Applications should be submitted to the Registrar, The University, Leeds LS2 9JT, no later than July 4, 1979, quoting reference number 72/6/D.

2227(A)

### UNIVERSITY OF STRATHCLYDE

Applications are invited from Honours graduates in appropriate disciplines for a

#### LECTURESHIP IN FORENSIC BIOLOGY (SEROLOGY)

in the FORENSIC SCIENCE UNIT in the DEPARTMENT OF PHARMACEUTICAL CHEMISTRY.

The person appointed will be expected to participate in postgraduate and undergraduate teaching, in research, and in consultancy work. Proven expertise in one or more of these areas is required and experience as a Biologist in a Forensic Science Laboratory would be a particular advantage.

Salary scale from October 1, 1979 £4,333 to £8,992 with placing according to qualifications and experience. Superannuation benefit.

Application forms and further particulars (quoting 32/79) and enclosing a self-addressed envelope (9in x 4in) may be obtained from the Academic Appointments Officer, University of Strathclyde, Royal College Building, 204 George Street, Glasgow, G1 1XW with whom applications should be lodged by July 2, 1979. 2206(A)

### THAMES POLYTECHNIC SCHOOL OF MATERIALS SCIENCE AND PHYSICS

#### DEPARTMENTAL SUPERINTENDENT GRADE 8

Applications are invited for the post of Superintendent who will be responsible for about 15 technicians who provide a complete technical support service for materials science and physics laboratories, electronics and mechanical workshops. The School has a substantial commitment to post-graduate courses and research in studies of the preparation, structure and properties of a wide range of materials involving the use of techniques such as optical microscopy, electron microscopy, X-ray analysis, electron spin resonance, ultra-violet and infra-red spectroscopy. Candidates should have substantial relevant experience and possess an appropriate H.N.D./H.N.C. qualification.

Salary scale: Technician Grade 8 £5,448 to £5,901 inclusive.

Further particulars and form of application may be obtained from the Staffing Officer, Thames Polytechnic, Wellington Street, London SE18 6PF, to whom completed applications should be returned by July 3, 1979.

2180(A)

### UNIVERSITY OF AUCKLAND New Zealand

#### SCHOOL OF MEDICINE

Applications are invited for the following vacant position. Conditions of Appointment and Method of Application are available from the Assistant Registrar (Academic Appointments), University of Auckland, or from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. Applications will be accepted at any time up to **AUGUST 10, 1979**.

Commencing salaries within the appropriate scale will be established in accordance with qualifications and experience up to the following maximums:

#### MEDICAL STAFF LECTURER

Maximum NZ\$17,335 per annum

The Auckland Hospital Board may make provision for a Lecturer undertaking clinical responsibilities after normal working hours to be paid an appropriate compensatory payment.

#### SENIOR LECTURER

Maximum NZ\$25,364 per annum

Senior Lecturer may be paid an appropriate allowance for clinical responsibilities.

#### ASSOCIATE PROFESSOR

Basic NZ\$27,000 per annum but in exceptional cases the Council may extend this to NZ\$30,495 per annum.

#### NON-MEDICAL STAFF LECTURER

Maximum NZ\$14,250 per annum

#### SENIOR LECTURER

Up to NZ\$16,780 per annum but in exceptional cases the Council may extend this to NZ\$18,300 per annum.

#### ASSOCIATE PROFESSOR

Basic NZ\$21,200 per annum

At present all salaries are supplemented by a General Wage Order of NZ\$365 per annum.

### PHARMACOLOGY AND CLINICAL PHARMACOLOGY

#### LECTURESHIP OR SENIOR LECTURESHIP (Medical or Non-Medical)

An especially well qualified candidate (non-medical) may be appointed at the level of Associate Professor. Applicants should have a postgraduate medical degree or qualification and/or a Ph.D. degree in Pharmacology, Clinical Pharmacology, Biochemistry or a related field and have proven ability to teach and conduct independent research. Preference will be given to those with training and active research interest in one of the following areas: pharmacokinetics (drug disposition and metabolism); passage of drugs across membranes; basic or applied autonomic, cardiovascular or respiratory pharmacology; basic or applied neurochemistry or neuropharmacology; basic or applied pharmacology related to anaesthesia. Candidates for a Lectureship or Senior Lectureship (medical) must hold a medical qualification registrable in New Zealand. It is possible that a medically qualified appointee may have clinical responsibilities in relation to the Auckland Hospital Board.

2255(A)

### LEGUME AGRONOMIST/ BACTERIOLOGIST

To participate in international field experiments to assess yield response of tropical legumes to inoculation with *Rhizobium*. Ph.D. in legume agronomy, physiology or bacteriology required. Must be prepared to travel extensively and have previous field experience with tropical legumes, and handling inoculants. Demonstrates ability to work on multi-disciplinary team would be an advantage. Applications to: Dr Jake Halliday, NITA Project of Hawaii, PO Box "O", Paia Hawaii 96779.

The University of Hawaii is an EEO/AA Employer. W175(A)

UNIVERSITY OF DUBLIN  
Trinity College

#### SCHOOL OF MATHEMATICS

Applications are invited for two Lectureships in the School of Mathematics, Trinity College, Dublin. These appointments arise as a result of a major new development in engineering education in the College. The persons appointed may be required to participate in this teaching programme.

#### LECTURESHIP IN APPLIED MATHEMATICS

Applications will be welcomed particularly from candidates with research interests in quantum field theory and its applications; or in astrophysics and cosmology or in any appropriate related fields.

#### LECTURESHIP IN PURE MATHEMATICS

Applications will be welcomed particularly from candidates with research interests in differential geometry; algebraic topology; numerical analysis or algebra, or in any appropriate related fields.

Salary scale: £4,317 to £8,487 per annum.

Appointment to each of the above posts may be made within the range £4,317 to £5,492 per annum, at a point commensurate with the qualifications and experience of the successful candidates. There is a non-contributory pension scheme.

Interested persons should, in the first instance, telephone the Staff Office, Trinity College on Dublin 772941, ext. 1678 or ext. 1775, or contact The Establishment Officer by Telex 5442 T.C.D. E1.

The closing date for receipt of completed applications will be Tuesday, July 10, 1979.

2254(A)

#### GRIFFITH UNIVERSITY

Brisbane, Australia

SCHOOL OF SCIENCE

#### READER

#### IN SCIENCE TECHNOLOGY AND SOCIETY

Applications are invited from qualified men and women for the senior academic appointment in the area of science technology and society (S.T.S.) within the School of Science. The appointee will have had extensive training and research experience in one or more aspects of the interaction of science with society. Applications from persons with interests in the effects of technological change and/or technology and underdevelopment would be particularly welcome. Undergraduate students in the School are required to study S.T.S. for a quarter of their time in the first year and optional courses are available in the later years. A coursework M.Sc. programme has taken its third cohort of students. The appointee will have considerable responsibilities in the teaching programmes and in the academic development of S.T.S. within the School. A Science Policy Research Centre (S.P.R.C.) has been established and the appointee will assume the position of Director of the S.P.R.C. The present salary for a Reader is £27,916. The University meets the cost of reasonable removal expenses. Applications close on August 20, 1979.

Intending applicants should obtain application procedure and further information from the Association of Commonwealth Universities (A.C.U.), Gordon Square, London WC1H 9PF.

The University reserves the right to make a fixed-term appointment.

2247(A)

## Head of Science Information Ware, Herts.

The Company is responsible for R & D of new ethical pharmaceuticals for the Glaxo Group. It is situated on two major sites at Greenford, Middlesex and Ware, Hertfordshire and employs about 1,500 staff.

We have an opportunity for an experienced information scientist to manage the Science Information and Library services to the whole Company.

The job will be based at Ware, where there is a well developed science information unit. This provides current awareness, information retrieval and central data services. We intend to expand the Greenford unit to provide similar services.

There will also be responsibility for establishing Company archives to house raw data, scientific samples, and reports. An important task will be to develop and maintain contacts with other information centres in the Glaxo Group.

Applicants must have extensive experience of information science gained at a senior level in a well established organisation. A biological background would be an advantage. He or she must also have a working knowledge of computerised information storage and retrieval techniques. It is unlikely that people below the age of 35 will have sufficient experience for this senior position.

The post carries a competitive salary, fully commensurate with its attendant responsibilities, and a company car is provided. Other benefits include pension, profit sharing and productivity schemes and extensive sports facilities. Assistance with relocation will be given where appropriate.

Please send your curriculum vitae, in confidence, to: Ian Collins, Ph.D., Personnel Manager, Glaxo Group Research Ltd., Ware, Herts. SG12 0DJ.

2237(A)

## Glaxo Group Research Ltd.

#### M.R.C. CLINICAL RESEARCH CENTRE (Northwick Park Hospital)

Watford Road, Harrow, Middx. HA1 3UJ

#### POSTDOCTORAL BIOCHEMIST

The Division of Immunochemical Genetics require a Postdoctoral Biochemist, preferably with experience in enzymology and protein chemistry for investigations of the glycosyltransferase of human blood group genes. This is a limited term appointment for four or five years. Depending on age and experience salary within the range £5,631 to £8,256 inclusive London Allowance.

Application form and further details may be obtained from Mrs J. Tucker-Bull. Please quote Ref. 134/1/4223. Closing date July 14, 1979.

2223(A)

#### UNIVERSITY OF READING PROFESSORSHIP OF HORTICULTURE

Applications are invited for the Professorship of Horticulture within the Department of Agriculture and Horticulture.

The Professor will be primarily responsible within the Department for the courses and research in Horticulture, and should be prepared to foster these within the larger area covered by the Department of Agriculture and Horticulture.

The appointment will be made from a date to be arranged with the successful candidate.

Further information may be obtained from the Registrar (Room 214, Whiteknights House), The University, Whiteknights, Reading RG6 2AH, by whom applications should be received not later than August 31, 1979.

2205(A)

#### UNIVERSITY OF NAIROBI—KENYA

Applications are invited for LECTURERS in the DEPARTMENT OF CROP SCIENCE.

Applicants should be holders of Ph.D. with specialisation in either Agricultural Statistics, Weed Science, Plant Breeding or Plant Physiology. Experience in teaching and research is essential. Holders of an MSc with experience may be considered. The appointee should participate in teaching undergraduate and postgraduate courses as well as research activities. Salary scale: Lecturer K£2016 to 3984 per annum (K£1=£1.18 sterling). The British Government may supplement salaries in range £4,278 to 4,818 per annum (sterling) for married appointees and £2,730 to 3,156 per annum (sterling) for single appointees (reviewed annually and normally free from tax) and provide childrens education allowances and holiday visit passages. Family passages; SSSF or FSSU; non-contributory medical scheme; subsidized housing/housing allowance; various allowances. Detailed applications (2 copies) with curriculum vitae and naming 3 referees to be sent direct to Registrar (Recruitment and Training) University of Nairobi, P.O. Box 30197, Nairobi, Kenya by July 30, 1979. Applicants resident in the UK should also send one copy to Inter University Council, 90/91 Tottenham Court Road, London, W1P 0DT. Further details may be obtained from either address.

2239(A)

## CSIRO AUSTRALIA Postdoctoral Research Fellow

### Division of Building Research Highett, Victoria

CSIRO has a broad charter for research into primary and secondary industry areas. The Organization has approximately 7,000 employees 2,400 of whom are research and professional scientists—located in Divisions and Sections throughout Australia.

FIELD: Planning and Management Studies.

GENERAL: The research programme of the Division includes research on planning, forecasting and technology assessment in the building industry as part of a more general programme of studies of the building industry and building development, utilizing systems and operations research techniques.

DUTIES: Carry out studies of building development and the building industry including technology assessment, industry stability studies and demand forecasting. Develop techniques to aid in planning, management and stabilization in the building industry.

QUALIFICATIONS: A PhD degree or equivalent in a relevant discipline together with demonstrable research ability. Applicants should preferably have an ability in mathematics, economics and/or computing techniques together with experience appropriate to the duties above.

SALARY: Research Scientist/Senior Research Scientist: \$A15422-\$A22405 pa.

TENURE: Term of 2 to 5 years.

Applications IN DUPLICATE, stating full personal and professional details, the names and addresses of at least two professional referees, and QUOTING REFERENCE NUMBER 390/613 should reach:—

The Personnel Officer, Australian Scientific Liaison Office, Canberra House, 10-16 Maltravers Street, London WC2R 3EH, by 20th July 1979.

Applications in U.S.A. and Canada should be sent to:—The Counsellor Scientific, Embassy of Australia, 1601 Massachusetts Avenue, N.W., Washington, D.C., 20036, U.S.A. 2244(A)

## MERSEYSIDE COUNTY MUSEUMS

# ASSISTANT KEEPERS

(FOUR POSTS)

- (A) BOTANY
- (B) INVERTEBRATE ZOOLOGY
- (C) SOCIAL AND INDUSTRIAL HISTORY
- (D) ETHNOLOGY

(£3,732 to £4,632 per annum, inc. supplement)

(Salary award pending)

Applicants for these posts, which are based at the County Museums, Liverpool, should possess a degree in an appropriate subject and/or the Museum Association Diploma. Experience of museum work or work in an associated field is desirable.

Candidates for posts (A) and (B) should have an interest in systematics and natural history, and for post (C) in military and social history, land transport or industrial archaeology. A knowledge of industrial culture and social anthropology with special interest in one geographical area is necessary for post (D).

Applications, giving details of experience and full curriculum vitae, should reach the Director, Merseyside County Museums, William Brown Street, Liverpool L3 8EN, by June 27, 1979. Tel: 051-207 0001. 2256(A)

UNIVERSITY OF DUBLIN  
Trinity College

### LECTURESHIP IN CHEMISTRY

Applications are invited for the above post in the Department of Chemistry, Trinity College, Dublin, tenable from September 1, 1979, or as soon as possible thereafter. This vacancy has arisen as a result of government-sponsored developments in engineering.

Current developments in the department include the setting up of studies of photoemission from adsorbates, and applicants with research interests in surface science or other related areas will be particularly welcome, but applications from candidates with interests related to any of the departmental fields of research will be carefully considered.

Salary scale: £4,317 to £8,487 per annum.

Appointment may be made within the range £4,317 to £5,492 per annum, at a point commensurate with the qualifications and experience of the successful candidate. There is a non-contributory pension scheme.

Interested persons should, in the first instance, telephone the Staff Office, Trinity College, on Dublin 772941, ext. 1678 or ext. 1775, or contact the Establishment Officer by Telex 5442 T.C.D. E1.

The closing date for receipt of completed applications will be Friday, July 27, 1979. 2252(A)

### UNIVERSITY OF BRISTOL LONG ASHTON RESEARCH STATION PLANT BREEDER

Required to be responsible in a small team for day-to-day organisation of an expanding strawberry breeding programme.

This will include the selection and breeding of improved varieties involving field trials at and beyond Long Ashton, investigating crop production methods, and disseminating information to advisers, growers and industry.

The work will also include some aspects of the Station's mutation breeding project on top and soft fruit plants and woody ornamentals.

Appointment in the Higher Scientific Officer (£4,101 to £5,448) or Senior Scientific Officer (£5,154 to £6,898) grade, salaries under review. Starting salary according to qualifications and experience. Non-contributory superannuation scheme.

Minimum qualifications: 2(i) Honours degree or equivalent in a botanical or horticultural subject, with at least two years' relevant post-qualifying experience. Applicants should have experience in plant breeding or biochemical/genetic techniques with a Ph.D. preferred.

Further particulars and application forms from the Secretary, Long Ashton Research Station, Bristol BS18 9AF, to whom applications should be sent by July 13, 1979. 2240(A)

### DEPARTMENT OF BIOCHEMISTRY UNIVERSITY OF NOTTINGHAM Queen's Medical Centre Nottingham NG7 2UH POSTDOCTORAL RESEARCH ASSISTANT

An M.R.C. financed position is available for three years from October 1, 1979 to work on "The Mechanism of Protein Degradation: studies on adipose tissue". A knowledge of protein chemistry, protein turnover or immunochemistry would be advantageous.

Starting salary £4,232 per annum. Candidates should write to Dr R. J. Mayer at the above address. 2177(A)

### CYCLOTRON UNIT MEDICAL RESEARCH COUNCIL

requires a physiologist or biologist investigate aspects of late radi damage to normal tissues. The is part of an extensive programme research into the relative effect X-rays and fast neutrons on no tissues and tumours at both clinical and experimental level. special concern are effects on nervous system and vascular dai and it will be an advantage if candidate has some previous experi working with either of these tissues.

The post is for 3 years. Mini qualifications are a good hon degree and a Ph.D or equivalent relevant subject.

Salary, according to age and perience, in the range £5,550 £7,129 (inclusive of London We ing), plus 6 weeks annual leave.

Please write, giving qualifica and curriculum vitae, to: Miss A Pires, M.R.C. Cyclotron Unit, I mersmith Hospital, Ducane R London, W12 0HS. Tel: 01-743 4 ext. 103. 2232(C)

### POSITION AVAILABLE APICULTURE UNIVERSITY OF GUELPH

The Department of Environm Biology, University of Guelph, been authorised to recruit a fa member to have major responsib for international programs Apiculture.

The position will be probatio at the Assistant or Associate Prof level on a tenure track.

Responsibilities of the position include the following:

- Direction of ongoing projects
- Apiculture in developing count
- Development of new projects in veloping countries and expansio existing ones to improve
- Apiculture.

- Training of students from devl ing countries.

- Participation in the teaching research programs of the De ment.

It is envisaged that the pos will be about 75% international volvement (50% directing projects 25% student training).

#### Qualifications

A Ph.D. or equivalent and field research experience in Apicul Willingness to travel extensively work in developing countries.

Salary will be commensurate experience. The minimum salary the Assistant Professor rank \$18,236, and for the Associate fessor rank \$23,055.

Contingent upon the availabil ity funds, the position will be avai January 1, 1980.

Applications should include a c plete resumé and the names of t referees and should be sent Chairman, Department of Env mental Biology, University of Guelph, Ontario, Canada N1G 2

Closing date: September 1, 1979 W174(C)

### UNIVERSITY OF STRATHCLYDE APPLIED GEOLOGY TECHNICIAN GRADE

required to undertake duties involv the operation and maintenance atomic absorption spectroph meters. Candidates with other chen laboratory experience will be gi sidered as training will be gi Applicants should hold an H.N.C equivalent qualification.

Salary Scale (including all sup ments): £3,474 to £4,056 per annu

Applications in writing, que reference GL.24, giving details of experience and qualifications, sh be made to The Personnel Off University of Strathclyde, Royal lege Building, 204 George St Glasgow G1 1XW. 2199(J)

# THE UNIVERSITY OF WESTERN AUSTRALIA

Perth

## SENIOR LECTURESHIP IN MATHEMATICS

Applications are invited for appointment as Senior Lecturer in the Department of Mathematics. The position is available from January 1, 1980, and the appointee will be expected to assume duty not later than June and preferably before March 1, 1980. Candidates should state in their applications the earliest date in 1980 on which they would be able to take up duty, if appointed.

Applications will be considered from persons with interests in the general area of probability and statistics, but some preference may be given to candidates with expertise and experience in applied statistics and consulting. If possible, the position will be filled at the level of Senior Lecturer, but a sufficiently well qualified and experienced candidate may be considered for appointment as Associate Professor.

The Department is responsible for courses in pure mathematics, applied mathematics and mathematical statistics up to Honours level, and postgraduate degrees may be taken in any of these areas. Further information concerning the Department and the research interests of its present staff may be obtained from the Chairman, Professor A. L. Blakers. Information concerning the statistical work of the Department, including statistical consulting and its possible development, may be obtained from Professor T. P. Speed.

The current salary ranges are: Senior Lecturer \$A21,180 to \$A24,687 per annum; Associate Professor \$A27,916 per annum. Benefits include superannuation similar to F.S.S.U., fares to Perth for appointee and dependent family, removal allowance, study leave and long service leave and housing loan scheme.

Applications in duplicate stating full personal particulars, qualifications and experience should reach the Acting Staffing Officer, University of Western Australia, Nedlands, Western Australia 5009, by August 18, 1979. Candidates should request three referees to write immediately to the Acting Staffing Officer, 2262(A).

## MEDICAL

### RESEARCH COUNCIL PNEUMOCONIOSIS UNIT

Llandough Hospital, Penarth  
South Glamorgan CF6 1XW

Applications are invited  
for a

Consultant grade post  
in

## RESPIRATORY MEDICINE

to carry out research into the cause, diagnosis, prevention and treatment of non-infectious extrinsic lung disease. The work includes the direction of a well staffed and equipped respiratory function research laboratory as well as the care of in and out patients at Llandough Hospital.

The successful applicant will be expected to pursue his or her own research as well as collaborate in projects involving other sections of the unit.

Applicants should be qualified to hold a consultant post in respiratory medicine and have special experience in the laboratory investigation of respiratory function. The successful applicant will be offered an unlimited appointment to the Council's clinical staff. Terms of employment will be those normal for M.R.C. clinical staff with honorary consultant sessions in the National Health Service. Salary present is £9,528 to £12,084 and compulsory pension scheme.

Applicants should contact the Director, M.R.C. Pneumoconiosis Unit, from whom further information and an application form may be obtained. Closing date: August 1, 1979. 2203(A)

## AERONAUTICAL RESEARCH LABORATORIES Australian Department of Defence

# Chief Superintendent

### Salary:

\$Aust. 34,066 (at present exchange rate £1 = \$A1.85).

### Location:

Melbourne, Australia.

### Duties:

In accordance with approved policies, undertake the management and scientific direction of the activities of the Aeronautical Research Laboratories.

In particular:

- Direct the implementation of the approved research and development programme, continuously review the programme and advise on any changes considered necessary.
  - Initiate and develop proposals for new items and/or activities for inclusion in the programme.
  - Accept responsibility as allocated for the scientific direction of major projects including extra mural activities.
  - Provide an advisory, consultative, standards and calibration service to the defence services, Australian and State Government departments and instrumentalities and industry, and direct the conduct of research and investigations in support of this service.
- Represent the Defence Science and Technology Organisation on committees, etc. as directed.

### Qualifications:

A degree in science or engineering combined with long experience in research and development. The position requires a person who has proven ability to manage scientific laboratories and to evolve research programmes to match defence needs.

The Aeronautical Research Laboratories are located at Fishermen's Bend, a suburb of Melbourne, the capital city of the State of Victoria.

Conditions of permanent appointment for the successful applicant and family include first class air travel to Australia, assistance with removal expenses and temporary rental assistance on arrival in Australia. Conditions of service include four weeks annual leave and accumulating sick leave benefits as well as a comprehensive superannuation scheme.

Detailed information relating to these conditions may be obtained from the Office of the Public Service Board Representative, Australia House, Strand, London WC2 (Telephone: 01-438 8448). Further information regarding this position can be obtained from Professor P T Fink, Chief Defence Scientist, Department of Defence, Russell Offices, Canberra A C T, Australia 2600. Applications detailing professional qualifications and experience should be forwarded to the Chief Defence Scientist by 31 July 1979. 2213(A)

# Australia

## THE UNIVERSITY OF LIVERPOOL

Walter Myers Chair of  
Parasitology

Applications are invited for the Walter Myers Chair of Parasitology, a full-time Chair in the Liverpool School of Tropical Medicine. The appointment will be made either as a clinical appointment, in the case of the successful candidate having a registrable medical qualification, or as a non-clinical appointment.

The salary will be up to £12,084 per annum (under review) in the case of a clinical appointment, or not less than £11,484 per annum (non-clinical appointment).

Applications (15 copies), together with the names of three referees, should be received not later than July 30, 1979 by the undersigned from whom further particulars may be obtained. (Candidates overseas may send only one copy by airmail.) Quote Ref RV/657/N. H. H. Burchinal, Registrar, The University, P.O. Box 147, Liverpool, L69 3BX. 2226(A)

## University College Hospital Medical School

Applications are invited for the post of

# Senior Lecturer

in Oral Microbiology (non-clinical) within the Dental School. The duties include teaching oral microbiology and assisting in the teaching of general microbiology to dental students. The successful applicant will be expected to conduct research, particularly on the bacteriology of periodontal disease and the metabolic activities of plaque organisms in dental caries.

Applications, with the names of two referees, to the Dean of Dental Studies, University College Hospital Dental School, Mortimer Market, London WC1E 6JD, within three weeks of the date of this advertisement. 2220(A)

# Experimental Scientists

## Neutron Beam Research

A new intense source of pulsed neutron beams, the spallation neutron source, is being built at the Rutherford Laboratory for use in research programmes of UK universities and polytechnics. A substantial number of neutron scattering instruments will be provided based on the time-of-flight method and outline designs have already been completed for the first seven. A wide range of equipment and techniques is involved; for example, position sensitive detectors for epithermal neutrons; high resolution choppers; sample environments controlling parameters such as temperature, pressure, magnetic field; neutron guides; neutron polarisation systems.

There are vacancies for support staff to participate in the development and provision of this equipment in the Neutron Beam Research Programme, which is expanding to meet the requirements for efficient utilisation of the SNS. When fully operational, in the 1980's, the SNS will be a world class facility serving a very widely based scientific community. As part of their development activities those appointed will have opportunities to work with research scientists using instruments at Harwell and the Institut Laue-Langevin, Grenoble. In addition, close collaboration is maintained with laboratories in the USA and elsewhere where spallation sources are being built. Applications should have HNC or HND and relevant experience or degree in physics or applied physics. Some experience in fields such as electronics, high vacuum, or cryogenics would be an advantage. Appointments will be made to permanent positions in the Science Group at the level of Scientific Officer or Higher Scientific Officer. Salary scales (at present under review).

Scientific Officer £3,037-£4,724.

Higher Scientific Officer £4,388-£5,820.

John Dalton Faculty of Technology

## HEAD OF DEPARTMENT OF BIOLOGICAL SCIENCES (GRADE VI)

Candidates should be well qualified academically and have research/industrial experience.

Qualities of academic leadership and administrative ability are essential.

The Department operates high level courses in B.Sc./B.Sc. Hons. Biological Sciences, H.N.D. Applied Biology, M.I.Biol., H.N.C. and Fellowship in Medical Laboratory Sciences, and Biology in the B.Sc./B.Sc. Hons. Combined Studies degree, and co-operates actively with other Faculties and Departments on a variety of courses.

Salary scale: £9,345 to £10,305.

For further particulars and application form (returnable by July 31, 1979) please send a self-addressed envelope marked "T/477" to the Secretary, Manchester Polytechnic, All Saints, Manchester M15 6BH. 2212(A)

LONDON SCHOOL OF  
HYGIENE AND TROPICAL  
MEDICINE

(University of London)

Keppel Street, WC1 7HT

DEPARTMENT OF MEDICAL  
MICROBIOLOGY

A MEDICAL LABORATORY  
SCIENTIFIC OFFICER

is required to work up to one year on the viruses of African haemorrhagic fevers. Candidates must be graduates or hold HNC/HND or an equivalent qualification and have had experience in electron microscopy. Inclusive salary, depending on experience, rises to a maximum of £4,284 (under review). Pensionable employment. Applications, consisting of full career and education details and naming two referees, should be sent to Secretary (A1) at the School. 2238(A)

LEICESTER POLYTECHNIC  
SCHOOL OF CHEMISTRY

Applications are invited for four posts to study for C.N.A.A. Ph.D. degrees in a small, well motivated and friendly department in which twenty research students are investigating problems in six main areas. These posts are renewable for a maximum of three years.

Post No. 1

POLYMER AND  
ADHESION SCIENCE

The object is to elucidate the mechanisms by which water affects the durability of epoxide-metal adhesive joints. The programme, which is directed towards aerospace applications, will be supervised by Dr John Comyn and Dr Derek Brewis.

Post No. 2

ELECTROCHEMICAL  
OXIDATIONS OF  
ORGANIC COMPOUNDS

It is hoped to replace such oxidising agents as permanganate and dichromate, which cause severe effluent problems in the pharmaceutical and other industries, by electrochemical grown metal oxide films and porous electrodes. The programme is supervised by Dr Robert Latham and Dr Ralf Dahm.

Post No. 3

SOLID STATE  
ELECTROCHEMISTRY

The aim is to study fundamental aspects, especially of the interface within the cell, of certain silver-copper and other novel battery systems. The programme is supervised by Dr Roger Linford.

Post No. 4

SOLID STATE  
BATTERY SYSTEMS

The project involves the study of solid state battery systems based on novel ionic conductors. The programme is supervised by Dr Roger Linford.

Salary for posts 1-3:

£2,673 per annum plus annual increments, including six hours/week demonstrating/teaching. These are L.E.A. Research Assistantships.

Salary for post 4:

This is a studentship provided by Mallory Batteries (U.K.) Ltd., pre-employment value £2,150 per annum tax free.

Application forms and further details from the Staffing Office, Leicester Polytechnic, P.O. Box 14 Leicester LE1 9BH; informal enquiries to Roger Linford, Reader in Chemistry (0533 50181, extn. 2202). 2201(P)

THE ROYAL  
VETERINARY COLLEGE  
University of London  
Division of Preclinical Studies  
DEPARTMENT OF PHYSIOLOGICAL  
POSTDOCTORAL  
RESEARCH ASSISTANT

Applications are invited for the above post which is expected to last for three years supported by grant from the Medical Research Council for a project on the interaction between general anaesthetics and neurotransmitters in the spinal cord under the direction of Dr David Lodge.

Applicants should have experience in micro-electrode recording and micro-iontophoretic techniques. They should contact Professor M. G. J. Jukes, Head of Department, or (after July 12) Dr David Lodge, Senior Lecturer, as soon as possible.

Salary £4,858 to £5,342 per annum including London Allowance according to qualifications and experience. Superannuation under the University scheme.

Application form from the Assistant Secretary (Personnel), The Royal Veterinary College, Royal College Street, London NW1 0TU. Telephone 01-387 2898. 2194(A)

## Wyeth Institute of Medical Research

### Gastroenterology

We are seeking to appoint a graduate physiologist or pharmacologist with two or more years experience of research on drugs which affect gastric secretion.

This post could be suitable for someone completing a second degree. The successful applicant will join an existing team which is committed to the discovery and development of new treatments for peptic ulcers. We are looking for someone who will be able to make an immediate contribution to the work of the section.

Please apply to:

Mrs. J. Andrews, Personnel Officer,  
**Wyeth Laboratories,**  
Huntercombe Lane South, Taplow,  
Maidenhead, Berks. Tel. Slough 28311.

## Wyeth Laboratories

2258(A)

### UNIVERSITY OF MAINE AT ORONO DEPARTMENT OF ZOOLOGY ASSISTANT PROFESSOR VERTEBRATE ECOLOGIST

Position to begin September 1, 1979. Salary \$13,000. Ph.D. required. Anticipated teaching responsibilities: part of undergraduate vertebrate biology course, alternate year avian biology and mammalogy, and graduate level community ecology. Conduct research in community ecology, with emphasis on birds and/or mammals.

Send credentials, reprints, and three letters of reference to: Dr Franklin L. Roberts, Chairman, Department of Zoology, University of Maine, Orono, Maine 04469. Deadline for receipt of applications May 20, 1979.

An Affirmative Action/Equal Opportunity Employer. W178(A)

### UNIVERSITY OF HAMBURG INSTITUT FÜR PHYSIOLOGISCHE CHEMIE ABTEILUNG ZELLBIOCHEMIE Applications are invited for the post of POSTDOCTORAL RESEARCH FELLOW

The post which is financed by the Deutsche Forschungsgemeinschaft is for work on biosynthesis of specific peptides and proteins from brain and particularly suitable for someone with experience in peptide analysis (sequencing and synthesis). Salary approximated DM37,000. Applications, together with the names and addresses of two referees should be forwarded to Prof. Dr D. Richter, Universität Hamburg, Institut Physiologische Chemie, 2 Hamburg Martinistr. 52, Pav. 53, Germany. W180(A)

### ODENSE UNIVERSITY DENMARK

A new position as Professor in Photosynthesis has been created in the Institute of Biochemistry, and is available for occupation as soon as possible.

It is desired to appoint a person whose research activities are experimental investigations of the functions of the photosynthetic membrane systems in eukaryotes and/or prokaryotes. A part of the current research in the Institute is concerned with electron transport in respiratory and photosynthetic systems, and the Institute is well equipped with special apparatus for this type of work.

The successful applicant will be expected to participate in the teaching programme of the Institute, which includes elementary courses common to science and medical students, advanced courses for science students and supervision of advanced project work.

Further information is obtainable from Institute of Biochemistry, Odense University, telephone (09) 15 86 00, ext. 2441.

The application should contain information about the candidate's teaching experience. It is expected that the successful applicant will eventually be able to teach in Danish.

The employment field covers the Ministry of Education and the institutions under it. The wage frame is 37, and the salary amounts to Danish Kroner 230,520.24 a year inclusive of bonuses as per the October 1, 1978.

A professional selection committee will discuss the applications and their recommendation will be sent out to all applicants in its complete form.

Application in 5 copies, marked "Position No. 745" enclosing curriculum vitae and documentation for professional and pedagogical activities must be made to the Queen and sent together with all enclosures also in 5 copies to: Journalkontoret, Odense University, Campusvej 55, DK 5230 Odense M, Denmark, so that we will receive it by October 1, 1979 at the latest. W173(A)

# SCHERING erwartet Sie

Für das Department Entzündungspharmakologie  
unserer Pharma Forschung suchen wir einen

## Mediziner/Medizinerin oder Biologen/Biologin

als Leiter einer wissenschaftlichen Arbeitsgruppe.

Wir gehen davon aus, daß sich aus den Erkenntnissen der immunbiologischen Grundlagenforschung Impulse zur Therapie bisher unzulänglich behandelbarer Erkrankungen ergeben werden.

Wir wünschen uns einen Mitarbeiter, der aufgrund seiner mehrjährigen experimentellen Erfahrung in der Lage ist, sich an dieser Grundlagenforschung zu beteiligen. Der Schwerpunkt seiner wissenschaftlichen Arbeiten wird auf dem Gebiet der Immunologie und Molekularbiologie liegen; dort wird die Basis für eine spätere Etablierung von Modellen zur Wirkstofffindung gelegt.

Wenn Sie an dieser Aufgabenstellung interessiert sind, bewerben Sie sich bitte schriftlich mit den üblichen Unterlagen oder rufen Sie uns an (Tel.: 030/468 28 53 oder 468 29 22).

SCHERING AKTIENGESellschaft  
Personalabteilung Berlin  
Müllerstraße 170-178, 1000 Berlin 65

# SCHERING AG

W172(A)

### CHARING CROSS HOSPITAL MEDICAL SCHOOL (University of London) GRADUATE RESEARCH ASSISTANT

(Biochemistry/Cell Biology)

Applications are invited for the above post in the Department of Experimental Pathology to assist in a two-year project on collagen synthesis in experimental renal fibrosis. The starting salary will be £3,689 plus £502 London Weighting. Further details may be obtained from Dr M. Barrett, telephone 01-748 2040 ext. 2761.

Applications on forms obtainable from The Secretary, Charing Cross Hospital Medical School, The Reynolds Building, St. Dunstan's Road, London, W6 8RP to be submitted by July 6, 1979. (Ref: 013/4). 2229(A)

### HERPETOLOGIST HARVARD UNIVERSITY

seeks to make a tenure-track appointment in herpetology of an assistant or associate professor in The Department of Biology who will serve conjointly as an assistant or associate curator in The Museum of Comparative Zoology. Preference will be given to candidates with (1) a strong research program in herpetology, (2) ability to offer instruction at the undergraduate and graduate levels, and (3) commitment to supervise and enhance a major herpetological collection. The closing date for receipt of applications is October 15, 1979, and the appointment will take effect July 1, 1980. Applicants should send a curriculum vitae, statement of research interests, and names of three references to: Herpetology Search Committee, Office of the Chairman, Department of Biology, Harvard University, Cambridge, Massachusetts 02138. Harvard is an Equal Opportunity/Affirmative Action Employer. W176(A)

# CSIRO AUSTRALIA

## Postdoctoral Research Fellow Division of Horticultural Research Adelaide

CSIRO has a broad charter for research into primary and secondary industry areas. The Organization has approximately 7,000 employees 2,400 of whom are research and professional scientists—located in Divisions and Sections throughout Australia. FIELD: Salinity Research.

GENERAL: The Division is concerned with research on a range of perennial horticultural plants (deciduous and evergreen) from both temperate and subtropical regions. Current programmes include studies on the management and genetic improvement of grapevines and fruit trees and of plant viruses and plant parasitic nematodes. Research in plant physiology, biochemistry and cytology relates to photosynthesis, salinity and plant and fruit development.

LOCATION: The Division has laboratories at Adelaide, South Australia (Headquarters); and Merbein, Victoria. The appointee will be located at the Merbein laboratory.

DUTIES: To develop and select salt tolerant crop plants in collaboration with plant physiologists. Experimentation would involve annuals as well as perennial horticulture species.

QUALIFICATIONS: A Ph.D. degree in plant breeding and genetics, or equivalent qualifications.

SALARY: Research Scientists or Senior Research Scientist: \$A14829-\$A21543 pa.

TENURE: 3 years. Superannuation available.

Applications in DUPLICATE, stating full personal and professional details, the names and addresses of at least two professional referees, and QUOTING REFERENCE NUMBER 491/052 should reach:—

The Personnel Officer, Australian Scientific Liaison Office, Canberra House, 10-16 Maltravers Street, London WC2R 3EH, by 20th July 1979.

Applications in U.S.A. and Canada should be sent to:—The Counsellor Scientific, Embassy of Australia, 1601 Massachusetts Avenue, N.W., Washington, D.C., 20036, U.S.A. 2243(A)

## THE MIDDLESEX HOSPITAL MEDICAL SCHOOL

(University of London)

SUB-DEPARTMENT OF

MOLECULAR BIOPHYSICS

DEPARTMENT OF

NUCLEAR MEDICINE

W.H.O. Collaborating Centre

for

Research and Reference Services

in the

Immunoassay of Hormones

in Human Reproduction

Applications are invited from

**BIOCHEMISTS**

experienced in radioimmunoassay and related techniques for a vacant post in the Supra-regional Assay Service Laboratory. The successful applicant will be primarily responsible, in collaboration with a senior endocrinologist, for the day-to-day running of the routine radioimmunoassay laboratory. He/she will, in addition, play a principal role in the development of new immunoassay techniques and the application of new and conventional methodologies for the assay of hormones and other substances of biological importance.

The appointment will be governed by University Conditions and Terms of Service, with starting salary at an appropriate point on the Lecturer Scale, £4,761 to £8,424 per annum, inclusive of £502 per annum London Allowance.

Applications, including a curriculum vitae and the names and addresses of two referees, to Professor R. P. Ekins, Department of Nuclear Medicine, The Middlesex Hospital Medical School, WIN 8AA. 2195(A)

## UNIVERSITY OF LIVERPOOL

Department of Organic Chemistry

**TECHNICIAN**

to assist with work concerning fungal biosynthesis. A major interest in microbiological techniques is preferable and knowledge of chemistry advantageous. Candidates must possess O.N.C. or equivalent as minimum qualification, but applications from candidates holding H.N.C. or degree with some previous laboratory experience will be welcomed.

Initial salary within a range up to £3,708 per annum according to qualifications and experience. Application forms available from the Registrar, The University, P.O. Box 147, Liverpool L69 3BX. Quote Ref: RV/654/N. 2224(A)

## THE UNIVERSITY OF LIVERPOOL

Selwyn Lloyd Chair of  
Medical Entomology

Applications are invited for the Selwyn Lloyd Chair of Medical Entomology, a full-time Chair held in the Liverpool School of Tropical Medicine. The appointment will be made as a non-clinical appointment. The salary will be not less than £11,484 per annum.

Applications (15 copies), together with the names of three referees, should be received not later than July 26, 1979 by the undersigned from whom further particulars may be obtained. (Candidates overseas may send only one copy by airmail.) Quote Ref RV/659/N. H. H. Burchall Registrar, The University P.O. Box 147, Liverpool, L69 3BX. 2225(A)

## THE POLYTECHNIC OF WALES Politechnig Cymru

Applications are invited for the following post:

### LECTURER II/ SENIOR LECTURER

DEPARTMENT OF SCIENCE

The person appointed, who will be a Microbial Physiologist/Microbial Biochemist will be required to teach up to B.Sc. (Honours) level and should have a higher degree together with relevant research, teaching or industrial experience. In addition he/she will be expected to undertake research.

Salary £4,101 to £7,065 (bar) to £7,572 (subject to review with effect from April 1, 1979).

Application forms and further particulars available from:

The Personnel Officer,  
The Polytechnic of Wales,  
Pontypridd,  
Mid Glamorgan,  
CF37 1DL.

Closing date: July 9, 1979.

2202(A)

## THE POLYTECHNIC OF CENTRAL LONDON BIOMEDICAL RESEARCH GROUP RESEARCH ASSISTANT

Salary £3,087 to £3,261 inclusive of London Allowance

A vacancy exists for a Research Assistant (3 year appointment) to work on brain evoked responses to sensory stimuli in neonates. The project will be carried out jointly with University College Hospital, London. The successful candidate, if suitably qualified, will be able to register for a higher degree (M.Phil. or Ph.D.).

Closing date: Two weeks after appearance of advertisement.

Application form and further details from the Establishment Officer, PCL, 309 Regent Street, London W1R 8AL (Tel. 01-580 2020, ext. 212).

2207(A)

## UNIVERSITY OF MALAYA

Applications are invited for the following Chairs:

Faculty of Science

**CHAIR OF GEOLOGY**

Faculty of Engineering

**CHAIR OF BIOCHEMICAL**

**ENGINEERING**

Computer Centre

**Qualifications and Experience:** Candidates should possess: a Ph.D. in the required field with:—(a) three years' experience as Senior Lecturer/Reader/Associate Professor; or (b) five years' experience as Lecturer; or a Master's degree in the required field with:—(a) five years' experience as Senior Lecturer/Reader/Associate Professor; or (b) eight years' experience as Lecturer.

Candidates are also required to undertake research and to have publications of academic standing.

**Salary Scales** (All inclusive [approx. stg. equiv.]: £8,313 by £420 to £8,733/Review Point/£9,014 by £420 to £9,434 per annum.

Further particulars and application forms are obtainable from the Association of Commonwealth Universities (Acpus), 36 Gordon Square, London WC1H 0PF.

The closing date for the receipt of applications is July 20, 1979.

2217(A)

## THE UNIVERSITY OF TORONTO ASSISTANT PROFESSOR IN BIOCHEMISTRY

Applications are invited for positions of Assistant Professor in Department of Biochemistry (or be located in the Playfair Unit in the Department of Biochemistry) to take effect July 1, 1980. Both appointees will be on a two-year contract with possibility of renewal for a further three years. The successful applicants will be required to take part in the tea programs of the Department and develop a research program. The appointment to the Playfair Unit will be made in the area of membrane receptor biochemistry; the other position has no field restrictions. Department is involved in tea Biochemistry to undergraduates in Faculties of Medicine, Dentistry, and Science, and Nursing, as well as graduate students. The minimum salary for both positions will be \$18,000.00.

Applicants with suitable qualifications should send a curriculum vitae and the names and addresses of referees to: Chairman of the Selection Committee, Department of Chemistry, University of Toronto, Canada, M5S 1A8, to him not later than September 1979. W182

## UNIVERSITY OF NEBRASKA-LINCOLN DEPARTMENT OF PLANT PATHOLOGY RESEARCH ASSOCIATE

Two Postdoctoral Fellows for temporary positions (2 years) available September 1979.

(1) Methodology involves separation of proteins by gel electrophoresis identifying Fe proteins by autoradiography.

(2) Study transmission of mosaic virus by the Mexican beetle. Transmission of electrophoretic forms will be compared and far radio labelled virus will be studied.

Salary about \$13,000/year. Send application or request details from L. C. Lane, Plant Pathology Department, The University of Nebraska-Lincoln, Lincoln, Nebraska, (402-472-3165) Affirmative Action Equal Opportunity Employer. W185

## UNIVERSITY OF SYDNEY LECTURESHIP IN ANIMAL HUSBANDRY (Animal Genetics)

Candidates should be graduates in Veterinary Science, Agriculture, Science, Rural Science or equivalent with a higher degree in field quantitative genetics, animal breeding or population genetics. Appointee responsible to Head of Department of Animal Husbandry for courses in Veterinary Science, Agriculture. He/she will also be expected to participate in the programme of research and postgraduate training in quantitative animal breeding and population genetics conducted within the Department.

The position is expected to be held by a probationary appointee for three years, capable of leading tenure, but if all the University requirements for tenure are met, tenure may be granted at the time of appointment.

Salary range: \$A15,786 to \$A2 per annum.

Applications, including curriculum vitae, list of publications and names of three referees, by August 31, to the Registrar, University of Sydney NSW 2006, Australia, from whom further information available. Information also available from Association of Commonwealth Universities (Acpus), 36 Gordon Square, London WC1H 0PF. 21861

# UNIVERSITY OF SYDNEY LECTURESHIP IN MATHEMATICAL STATISTICS

Preference given to applicants interested in one or more of: Statistical Inference, Robustness, Time Series, Statistical Computations, and in applications to analysis of data. Teaching capability will be an important consideration.

The position is expected to be filled by a probationary appointment of three years, capable of leading to tenure, but, if all the University's requirements are deemed to be satisfactorily met tenure may be granted at the time of appointment.

Salary range: \$A15,786 to \$A20,737 per annum.

Applications, including curriculum vitae, list of publications and names of three referees by July 31, 1979 to the Registrar, University of Sydney, NSW 2006, Australia, from whom further information available. Information also available from Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. 2187(A)

# UNIVERSITY OF HONG KONG CLINICAL BACTERIOLOGIST

Applications are invited for a post of Clinical Bacteriologist in the Department of Microbiology. Applicants with a medical qualification and suitable laboratory experience are preferred though a science graduate with experience in hospital microbiology service will also be considered.

Annual salaries (superannuable) are: Medically qualified: HK\$63,900-71,140 - 74,100 - 81,540 - 85,320 BAR 02,780 - 107,340 - 111,960 - 116,580 - 121,200.

Non-medically qualified: HK\$46,260 - 43,200 - 63,540 x 4,260 - 72,060 BAR 6,320 x 4,260 - 106,140. (£1 equals HK\$10.30 approx.).

Starting salary will depend on qualifications and experience.

At current rates, salaries tax will not exceed 15 per cent of gross income. Housing at a rental of 7½ per cent of salary, education allowances, long leave and medical benefits are provided.

Further particulars and application forms may be obtained from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, or the Assistant Secretary (Recruitment), University of Hong Kong, Hong Kong. Closing date for applications is July 1, 1979. 2192(A)

# DEVELOPMENTAL BIOLOGISTS

The Department of Biology of The Johns Hopkins University has 2 faculty positions available. One of these positions is at the assistant professor level while the other may be any level. Individuals interested in research and teaching in the cellular, genetic and/or molecular aspects of developmental biology are invited to apply.

Applications will be accepted until September 30, 1979. Send curriculum vitae, bibliography and a description of research interests to:

Chairman, Developmental Biology Search Committee  
Department of Biology  
The Johns Hopkins University  
Baltimore, Maryland 21218

The Johns Hopkins University is an Equal Opportunity Employer and does not discriminate on the basis of race, colour, religion, national origin, age, sex, veteran status, handicap, or any other occupationally irrelevant criteria. W183(A)

# WELSH NATIONAL SCHOOL OF MEDICINE (University of Wales) TENOVUS INSTITUTE FOR CANCER RESEARCH

Applications are invited for the post of

## SENIOR LECTURER

in Cancer Research (Steroid Biochemistry) in the above Institute at Heath Park, Cardiff. Candidates must have considerable research experience in steroid biochemistry and expertise in surgical procedures would be advantageous.

Salary on the scale for Non-clinical Senior Lecturers £8,182 to £10,097 per annum (under review); starting point dependent upon qualifications and experience.

Further particulars available from the Registrar and Secretary, Welsh National School of Medicine, Heath Park, Cardiff, to whom applications should be submitted one month from the appearance of this advertisement. 2214(A)

# UNIVERSITY OF BRISTOL DEPARTMENT OF BOTANY

Applications are invited for the post of

## N.E.R.C. RESEARCH ASSISTANT

in Palaeobotany to work on a monograph of Devonian megaspores under the supervision of Dr K. C. Allen. This appointment will be for three years. Applicants should hold, or expect to obtain, a good Honours Degree in either Botany or Geology. The starting salary will be £3,689 per annum (subject to revision on October 1, 1979) and will commence on or around September 1, 1979.

Applications, including a curriculum vitae, giving the names and addresses of two referees should be sent to Miss Suzy Oakes, Department of Botany, The University, Woodland Road, Bristol BS8 1UG not later than July 5, 1979. 2215(A)

# THE UNIVERSITY OF MANCHESTER Oxford Road Manchester M13 9PL GRADE 4 TECHNICIAN

required in the Electron Microscope Unit of the Department of Botany and Zoology. Applicants should have at least O.N.C. or equivalent qualification and preferably H.N.C. and have had six years' relevant experience including ultramicrotomy and other preparatory techniques.

Salary scale: £3,222 to £3,708 per annum.

Applications with full details of age, qualifications and previous experience should be sent as soon as possible to Doctor R. Butler, Department of Botany. 2235(A)

# UNIVERSITY OF LONDON READERSHIP in Probability and Statistics at University College London

The Senate invites applications for the above Readership in the Department of Statistics and Computer Science, particularly from persons with research interests in data analysis. Salary at an agreed point on the scale £8,698 to £10,775 (from October 1979) plus £502 London Allowance. Applications (10 copies) must be received not later than July 13, 1979 by the Academic Registrar (N), University of London, Senate House, London WC1E 7HU, from whom further particulars should first be obtained. 2190(A)

# AUSTRALIAN NATIONAL UNIVERSITY

Applications are invited from suitably qualified persons for appointment to the following positions:

## RESEARCH SCHOOL OF BIOLOGICAL SCIENCES MOLECULAR BIOLOGY UNIT POSTDOCTORAL FELLOW

The Unit (Head, Dr H. Naora) is exploring the molecular mechanisms of post-transcriptional control in animal cells. This includes the problems of the mRNA-mRNA precursor-product relationship, the nuclear processing of mRNA-precursor molecules, using nucleic acid sequencing and DNA cloning. Applicants should have experience in this particular field of research.

CLOSING DATE: July 31, 1979.

## RESEARCH SCHOOL OF EARTH SCIENCES RESEARCH FELLOW IN GEOPHYSICAL FLUID DYNAMICS

The School wishes to make an early appointment to a third Research Fellowship in the Geophysical Fluid Dynamics Group. The Group comprises at present Professor J. S. Turner and two Research Fellows.

The research of the Group has been in two main areas: (i) laboratory and theoretical models of convection and mixing processes in the ocean and (ii) theoretical work on fluid dynamical processes in the interior of the Earth. The Group has also developed interests in fluid processes relevant to the formation of ore deposits and of layered igneous intrusions, and would consider further collaborative extensions of research into relevant fields of environmental geochemistry.

Applications are invited from candidates with qualifications in any of these fields. There will be excellent opportunities for the successful candidate to pursue interdisciplinary research with other groups in the School.

Applications should be sent as soon as possible.

## RESEARCH SCHOOL OF PHYSICAL SCIENCES MOUNT STROMLO AND SIDING SPRING OBSERVATORIES FELLOW (One position)

## RESEARCH FELLOW/SENIOR RESEARCH FELLOW (Two positions)

The Observatories expect to make one tenured appointment (Fellow) and one or two short term appointments (3 to 5 years as Research Fellow/Senior Research Fellow). Applications in all fields of observational and theoretical astrophysics will be considered. Astronomers interested in space research applications are encouraged to apply. Applications from senior astronomers who could accept an appointment for one or two years only are welcomed.

CLOSING DATE: August 31, 1979.

### Conditions of Appointment

Salaries: Salary will be in accordance with qualifications and experience within the range—Senior Research Fellow \$A22,049 to \$A26,301; Research Fellow \$A15,786 to \$A20,606; Fellow \$A18,401 to \$A24,652; Postdoctoral Fellow—a fixed point between \$A15,786 to \$A20,606 per annum. Present exchange rates are \$A1=UK£0.53, \$US1.10, \$C1.27.

### Term of Appointment

Fellow—five years in the first instance with the possibility of reappointment after review to age 65. Research Fellow/Senior Research Fellow—three years in the first instance with the possibility of extension to five years. Postdoctoral Fellow—not less than one year or more than two years.

### Other Conditions

Reasonable appointment expenses are paid. Superannuation benefits are available for applicants who are eligible to contribute. Assistance with finding accommodation is provided for an appointee from outside Canberra. The University reserves the right not to make an appointment or to make an appointment by invitation at any time.

Prospective applicants should obtain the further particulars from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, before submitting applications. 2191(A)

# UNIVERSITY OF ST ANDREWS DEPARTMENT OF ANATOMY AND EXPERIMENTAL PATHOLOGY

Applications are invited for the recently created post of

## LECTURER

in the Department of Anatomy and Experimental Pathology. The successful candidate will be expected to contribute to the teaching of

### CELLULAR PATHOLOGY.

Previous experience in a Department of Pathology or Experimental Pathology is therefore essential. Excellent facilities for research are available. The Department may be visited by arrangement with Professor D. Brynmor Thomas (Telephone St Andrews 72411).

Salary at appropriate point on scale £4,232 to £8,452 per annum (under review), starting salary not above £6,108, plus F.S.S.U./U.S.S.

Applications (two copies preferably in typescript) with the names of three referees should be lodged by July 9, 1979 with the Establishments Officer, The University, College Gate, St Andrews, Fife, from whom further particulars may be obtained. 2228(A)

# UMIST POSTDOCTORAL RESEARCH in IMAGE ANALYSIS

An image analysis unit is being developed within UMIST for the study of morphological and optical characteristics of cellulose fibres and paper sheets. A postdoctoral research position has arisen in this field which will involve the use of a recently acquired Joyce Loeb Magiscan Image Analyser. The position will have a research bias and be of 2 years' duration. The successful applicant is likely to have a background in physics, electrical engineering, mathematics or computing, but other disciplines would be considered. Salary will be in the range £3,883 to £6,555 per annum (which is subject to a revision from October 1978 and a further award from October 1979).

Applications by letter, quoting reference PFS/58/A1 giving curriculum vitae and the names of two referees should be addressed to Dr J. C. Roberts, Paper Science Building, UMIST, PO Box 88, Manchester M60 1QD. 2173(A)

## CSIRO AUSTRALIA

### Postdoctoral Research Fellow

#### Division of Protein Chemistry Parkville Victoria

CSIRO has a broad charter for research into primary and secondary industry areas. The Organization has approximately 7,000 employees 2,400 of whom are research and professional scientists—located in Divisions and Sections throughout Australia.

**FIELD:** Immunochemistry.

**GENERAL:** The Division has a research staff of some 60 biochemists, biophysicists, physical biochemists and organic chemists. The major role of the Division is to contribute to knowledge of the molecular structure and chemistry of proteins, particularly in areas where the molecular properties of proteins determine the commercial value of a product or where information is important for plant or animal production. Current research interests include wool, leather, plant proteins and biologically active proteins. Plant protein research is directed to the increased and more efficient utilization of seed protein from legumes in Australian agriculture and industry.

**DUTIES:** Initially, to study the characterization and assay of seed storage proteins using serological techniques and to provide immunological data for comparative studies of proteins from different sources. The person appointed will be encouraged to apply his/her knowledge of immunochemistry to other relevant research programmes within the Division.

**QUALIFICATIONS:** A PhD in an appropriate field with demonstrated research ability. Experience in the field of immunochemistry is essential.

**SALARY:** Research Scientist/Senior Research Scientist: \$A15,422-\$A22,405 pa.

**TENURE:** Fixed term of 3 years.

Applications IN DUPLICATE, stating full personal and professional details, the names and addresses of at least two professional referees, and QUOTING REFERENCE NUMBER 462/448 should reach:—

The Personnel Officer, Australian Scientific Liaison Office, Canberra House, 10-16 Maltravers Street, London WC2R 3EH, by 20th July 1979.

Applications in U.S.A. and Canada should be sent to:—

The Counsellor Scientific, Embassy of Australia, 1601 Massachusetts Avenue, N.W., Washington, D.C., 20036, U.S.A. 2245(A)

## AGRICULTURAL RESEARCH COUNCIL

### FOOD RESEARCH INSTITUTE

#### SCIENTIFIC SERVICES AND DEVELOPMENT DIVISION

### CHEMIST

A Scientific Officer is required to join, on a temporary basis, the Chromatography Development Group which is part of the Scientific Services and Development Division. The appointment relates to a research contract ending in October 1980, which has as its objective the estimation in poultry waste of residues of specified veterinary products. Published gas chromatographic methods will be worked up but some method development will be necessary.

A pass degree or H.N.C. in chemistry, together with a knowledge and practical experience of high performance liquid chromatography and/or gas chromatography, are required.

Salary: on a scale £2,839 to £4,415 (under review).

Five-day working week and flexible working hours scheme operated. Transport facility available mornings and evenings.

Further particulars and application forms from:

The Secretary, Food Research Institute, Colney Lane, Norwich NR4 7UA, quoting Ref. No. 79/9.

Closing date: July 4, 1979.

advertisement in these pages**

**Phone: 01-831-6901**

## NEW ZEALAND FOREST SERVICE

# Scientist

### PRODUCTION FORESTRY DIVISION, FOREST RESEARCH INSTITUTE, ROTORUA

Applications are invited for the above position. Salary up to \$16,685 (N.Z.) per annum depending on qualifications and experience.

A forest soils scientist is required to join a team of 8 scientists and 15 support staff studying tree nutrition, soil fertility and forest site productivity in New Zealand. A major part of the programme involves pinus radiata plantations and includes soil chemistry, soil physics, tree nutrition, nutrient cycling and biomass production.

Qualifications desired: PhD in soil science with supplementary training and experience in forestry, or PhD in forestry with supplementary training and experience in soil science.

Housing available for an initial 2 year period.

Successful applicants will receive assistance with fares and transfer of personal baggage to New Zealand.

Application forms may be obtained from:

**The Chief Migration Officer  
New Zealand House  
Haymarket  
LONDON  
SW1Y 4TQ**

You should quote reference Imm 2/326/6.

Closing date for applications: August 24th 1979.

Further particulars may be obtained from the Director, Production Forestry Division, Forest Research Institute, Private Bag, Rotorua, New Zealand.

2176(A)

## CHARING CROSS HOSPITAL (FULHAM)

### BIOCHEMIST

#### DEPARTMENT OF MEDICAL ONCOLOGY

Applications are invited from Chemists/Biochemists to join a project on synthesis and *in vivo* localisation of antibody conjugates relevant to diagnosis and therapy of cancer. Candidates should possess an appropriate science degree and experience of radioimmunoassay would be an advantage. The post will be supported by the Cancer Research Campaign and Whitley Council salaries and conditions for Probationary Grade Biochemists apply.

Further details from Dr F. Searle, Medical Oncology, tel: 01-748 2040, ext. 2320. Application forms from District Personnel Department, Charing Cross Hospital, Fulham Palace Road, London W6 8RF. Tel: 01-748 2040, ext. 2992.

2257(A)

**TECHNICIAN or JUNIOR TECHNICIAN** required by the Institute of Cancer Research in association with the Royal Marsden Hospital at Sutton, Surrey. Candidates should have an interest in cell culture and, ideally, some previous experience in this field and also in enzymology. The individual appointed will take part in a new M.R.C. Project on clinical and laboratory aspects of head and neck cancer, commencing September-October, 1979. Salary in scale £3,261 to £3,813 p.a. (Technician) or £2,169 to £3,015 p.a. (Junior Technician), plus London Allowance of £354 p.a. (scales under review). Salary will depend on age and qualifications, two 'A' levels in science subjects for Junior Technician and either a Degree, HNC or equivalent qualification for a Technician appointment. Applications in duplicate with the names of two referees to the Secretary, Institute of Cancer Research, 34 Sumner Place, London SW7 3NU, quoting ref. 301/B/73.

2174(A)

## UNIVERSITY OF LIVERPOOL DEPARTMENT OF ZOOLOGY

Applications are invited for the post of

### POSTDOCTORAL SENIOR RESEARCH ASSISTANT (Grade 1A)

to work on the mechanisms of ion transport in fish erythrocytes and the alterations of ion transport during salinity acclimation of fish. Techniques involved include isotope flux and cell culture.

Initial salary £4,232, £4,505 £4,776 per annum.

Applications, together with names of three referees, should be received not later than July 16, 1979 by The Registrar, The University, Box 147, Liverpool L69 3BX, from whom further particulars may be obtained. Quote Ref. RV/650/N.

2169(A)

REQUIRED BY THE  
FOOD AND AGRICULTURE  
ORGANIZATION OF THE  
UNITED NATIONS, ROME, ITALY

## CROP PROTECTION SPECIALISTS

(Phytopathologists, Entomologists, Weed Scientists)

to be stationed in Sahelian countries, serving in a large-scale project on Integrated Pest Management for Basic Food Crops implemented with the assistance of FAO by the Inter-States Permanent Committee for Drought Control in the Sahel (CILSS).

**ESSENTIALS:** Ph.D. in Plant Protection Sciences. At least 7 years of post-graduate experience in pest management. Good working knowledge of English or French.

**SALARY:** dependent on qualifications/seniority, net tax-free including the usual International Civil Service allowances. Please send detailed curriculum vitae quoting "TF/RAF/128(USA)-comm." to Mr T. Eshetu, Manpower Planning, AGO, FAO, Via delle Terme di Caracalla, 00100 Rome, Italy.

W184(A)

### BIOCHEMIST

Our Department of Biochemistry is seeking an experienced scientist to work in the field of drug metabolism with special reference to the skin.

The successful candidate will have:

- At least five years' postdoctoral experience (or the equivalent).
- *In vivo* and *in vitro* experimental ability in metabolism work, including the handling of labelled compounds. Experience in skin biochemistry would be advantageous.
- A practical knowledge of analytical chemical techniques (HPLC, GC, TLC and spectroscopy).

Our modern Research Centre based near Nice in the South of France, was recently created to study the skin and its disorders and is associated with a multi-national French Company.

For further details please send curriculum vitae to Box No. W181(A), c/o Macmillans Journals, 3 Dyers Buildings, Holborn, London EC1N 2NR.

### UNIVERSITY OF LIVERPOOL DEPARTMENT OF GENETICS

Applications are invited for the post of

#### POSTGRADUATE RESEARCH ASSISTANT

to work on an N.E.R.C. financed project to investigate genetic determination of abundance and polymorphism in a population of *Drosophila melanogaster*.

The project is financed for three years. Candidates should be graduates with a sound background in ecology, genetics or ecological or population genetics. A suitably qualified candidate may be allowed to register for a higher degree.

Applications, together with the names of three referees, should be received not later than July 12, 1979, by The Registrar, The University PO Box 147, Liverpool L69 3BX. Quote Ref. RV/648/N. 2168(A)

**INSTITUTE OF CANCER RESEARCH: TECHNICIAN or JUNIOR TECHNICIAN** required at the Sutton, Surrey laboratories for work with mammalian cell culture applied to radiobiology. Experience in cell culture methods would be an advantage but is not essential. Salary in scale £3,261 to £4,680 per annum. (Technician) or £2,169 to £3,015 per annum. (Junior Technician), plus London Allowance of £354 per annum (scales under review). Salary will depend on age and qualifications, two 'A' levels in science subjects for Junior Technician and a Degree, HNC or equivalent qualification for a Technician appointment.

Applications in duplicate with the names of two referees to the Secretary, Institute of Cancer Research, 34 Sumner Place, London, SW7 3NU, quoting ref. 301/B/74. 2222(A)

### ROYAL FREE HOSPITAL SCHOOL OF MEDICINE

(University of London)

Department of Neurological Science  
TECHNICIAN

Histological Technician required to work in EM neuropathology laboratory. Appointment for 3 years in first instance. Salary on Whitley Council Scale according to age and experience.

Further details and application form from the School Secretary, R.F.H.S.M., 8 Hunter Street, London, WC1N 1BP, or tel. 01-837 5385 ext. 54. Closing date for applications July 13, 1979. 2221(A)

**INSTITUTE OF CANCER RESEARCH** in association with the **ROYAL MARSDEN HOSPITAL**, Sutton, Surrey, require **JUNIOR TECHNICIAN** in the Department of Histopathology. Applicants should have a minimum of 5 'O' levels including Maths, English and two science subjects or (preferably) two science 'A' levels or ONC in Medical Laboratory Sciences.

Training will be given in all aspects of histological technique and Day-release will be granted.

Salary in scale £2,037 to £3,015 per annum depending on age and qualifications (scales under review), plus London Allowance of £354 per annum.

Applications in duplicate with the names of two referees to the Secretary, Institute of Cancer Research, 34 Sumner Place, London, SW7 3NU, quoting ref. 301/B/75. 2236(A)

### STUDENTSHIPS

#### UNIVERSITY OF LONDON REACTOR CENTRE ASCOT, BERKSHIRE

##### POSTGRADUATE RESEARCH STUDENTSHIPS

Applications are invited, from candidates holding, or expecting to obtain, a good honours degree, for the following research studentships tenable from October 1:

- (i) A Bursary Funded by the U.K.A.E.A. for a study of the Radioactive Decay Schemes of Actinide Isotopes in collaboration with the Nuclear Physics Division at A.E.R.E. Harwell.
- (ii) An S.R.C. Case Studentship in collaboration with the National Physical Laboratory for a project involving the measurement of Neutron Energy Spectra and Neutron Absorption Cross Sections in the Resonance Region.
- (iii) An N.E.R.C. studentship in collaboration with the British Museum (Natural History) for a study of the structural breakdown of Minerals by Radioactivity and involving the use of particle track mapping techniques.
- (iv) S.R.C. Quota Awards may be available for various other projects in fields such as Reactor Physics, Neutron Activation Analysis and Radiochemistry.

Those interested are invited to write or telephone, as soon as possible, for an application form and further details to:

Dr T. D. MacMahon, University of London Reactor Centre, Silwood Park, Sunninghill, Ascot, Berkshire SL5 7PY. (Telephone Ascot (0990) 23911 ext. 298) 2219(F)

#### IMPERIAL COLLEGE UNIVERSITY OF LONDON

DEPARTMENT OF CHEMICAL ENGINEERING AND  
CHEMICAL TECHNOLOGY

##### S.R.C. C.A.S.E. STUDENTSHIPS

for research with Dr G. C. Maitland into the following areas:

1. Elongational flow of polymer solutions in relation to enhanced oil recovery, in collaboration with B.P. Research Centre;
2. Mathematical modelling of P.V.C. polymerisation processes, in collaboration with I.C.I. Plastics Division.

Applicants should hold, or expect to obtain, a first or upper second class honours degree in a physical science or chemical engineering. The awards are tenable for three years at normal S.R.C. rates supplemented by up to £500 per annum by the sponsors.

All applications, including a curriculum vitae and the names of two referees, should be sent to:

Dr K. E. Bett  
Department of Chemical Engineering  
Imperial College  
London SW7 2BY

2261(F)

## STUDENTSHIPS—continued

# university college of swansea

## RESEARCH STUDENTSHIP

The Science Research Council is prepared this year to offer to suitable candidates a Research Studentship tenable in the Department of Geology or the Department of Oceanography at the above University College.

Applicants should have at least an upper second class honours degree in an appropriate science, or be expected to obtain such a degree by July, 1979, in order to pursue a research programme leading to a Ph.D.

The studentship will be tenable from October 1, 1979 and the value will be in line with current S.R.C. rates.

Further details about the research topics available and application forms may be obtained from the Secretary of the Department of Geology or Oceanography, University College of Swansea, Singleton Park, Swansea SA2 8PP. 2242(F)

## THE UNIVERSITY OF SHEFFIELD

DEPARTMENT OF MEDICINE

Man or woman

### BIOLOGY GRADUATE

minimum class II(i), wanted for Medical Research Council Studentship. Those expecting to graduate this summer may apply. A three-year award to study for a Ph.D. in respiratory physiology. Project concerns changes in the lung circulation in oxygen deficiency. Apply to the Registrar and Secretary, The University, Sheffield S10 2TN as soon as possible. Quote Ref. R/305/G. 2170(F)

## UNIVERSITY OF SOUTHAMPTON

DEPARTMENT OF  
NEUROPHYSIOLOGY

### RESEARCH STUDENTSHIP IN NEUROPHYSIOLOGY

A Research Studentship is available in Neurophysiology or Neuropharmacology. Applicants should have an Upper Second Class Honours Degree in an appropriate subject. Applications giving names and telephone numbers of two referees should be sent to Professor G. A. Kerkut, Department of Neurophysiology, School of Biochemical and Physiological Sciences, Southampton University, Southampton. 2175(F)

## UNIVERSITY OF NEWCASTLE

Department of Microbiology

### S.R.C. C.A.S.E.

### RESEARCH STUDENTSHIP

Applications are invited for a C.A.S.E. Studentship in co-operation with the Fish Diseases Laboratory, Weymouth to investigate the taxonomy and ecology of the causative agents of Bacterial Kidney Disease in Fish. Applicants should hold or expect to achieve at least an upper second class Honours Degree in Microbiology or have an equivalent qualification.

Applications with the names and addresses of two referees and a curriculum vitae should be sent to Dr M. Goodfellow, Department of Microbiology, The Medical School, The University, Newcastle upon Tyne NE1 7RU by June 30, 1979. 2233(F)

## THE HATFIELD POLYTECHNIC

BIOLOGICAL SCIENCES

### S.R.C. STUDENTSHIP

An S.R.C. Studentship is available in one of the following areas:

- (i) Viricidal effects in plant tissue cultures.
- (ii) Drug metabolism studies with isolated Hepatocytes.
- (iii) The pelleting of Actinomyces in submerged culture.
- (iv) *Microspora alaphoides*, Powdery Mildew on *Quercus robur*.

Applicants must possess a good honours degree in an appropriate subject and will be expected to register for a higher degree. There will be an opportunity to undertake some demonstrating to undergraduates.

For further details apply to Dr K. Wilson, Biological Sciences, The Hatfield Polytechnic, P.O. Box 109, Hatfield, Herts. AL10 9AB, enclosing a curriculum vitae and the names of two referees. 2211(F)

## UMIST

### S.R.C. C.A.S.E.

### STUDENTSHIP

The Science Research Council has made a co-operative award to the Department of Polymer and Fibre Science (Paper Science Section), UMIST, and the Research Association for the Paper and Board, Printing and Packaging Industry (PIRA).

The work will be concerned with investigations into the effects of non-cellulosic polysaccharides on pulp and paper properties. A successful applicant will be expected to submit for a higher degree and will spend some part of his training in the Research Department of PIRA. The maintenance grant is £2,320 per annum, which includes an annual contribution of £500 by PIRA.

Applications are invited from graduates with good honours degrees in Chemistry, Biochemistry or a related subject and should be made in writing, giving a curriculum vitae and the names of two referees, to Dr J. C. Roberts, Paper Science Building, UMIST, PO Box 88, Manchester M60 1QD. 2208(F)

DEPARTMENT OF BIOCHEMISTRY

## UNIVERSITY OF NOTTINGHAM

Queen's Medical Centre  
Nottingham NG7 2UH

### S.R.C. C.A.S.E.

### STUDENTSHIP

A C.A.S.E. studentship is available from October 1, 1979, to work on "Hormonal Regulation of Enzyme Turnover in Adipose Tissue". The project is to be carried out in conjunction with Dr R. G. Vernon, Department of Physiology, The Hannah Institute, Ayr, Scotland. Candidates should be prepared to work in both laboratories.

Candidates should write to Dr R. J. Mayer at the Nottingham address. 2178(F)

## UNIVERSITY OF CAMBRIDGE

### S.R.C. STUDENTSHIP

Applications are invited for the above studentship which is for geochemical or stable isotope geochemical studies of lunar samples and or meteorites.

Application together with names of two referees to Dr C. T. Pillinger, Department of Mineralogy and Petrology, Downing Place, Cambridge CB2 3EW. 2264(F)

## ROYAL HOLLOWAY COLLEGE

(University of London)

Egham Hill, Egham, Surrey

DEPARTMENT OF

BIOCHEMISTRY

POSTGRADUATE

STUDENTSHIP

S.R.C. C.A.S.E. studentship (tenable for three years and leading to Ph.D. degree) to undertake a study of the biochemistry of chill damage of bananas in conjunction with Geest Associates Ltd. The work will involve a variety of biochemical techniques and the student will spend four weeks per annum at Geest Associates in Spalding, Lincs. Candidates who have (or are likely to have) a class 1 or 2 (i) honours degree in: biochemistry; chemistry with a biological subject; botany with chemistry should write to Professor J. B. Pridham. 2246(F)

## THE CITY UNIVERSITY

DEPARTMENT OF

CHEMISTRY

### ENERGY RESEARCH

### S.R.C./C.A.S.E. AWARDS

Applications are invited for studentships for work on the following topics:

- (a)  $H_2$  production using renewable energy sources such as wave, solar, hydroelectricity as well as off-peak nuclear electricity. The work will involve the study of the electronic, crystallographic and electrochemical properties of semiconducting oxides and sulphides, and will be done in collaboration with the Central Electricity Research Laboratory, Leatherhead.

- (b) Mechanism of stress corrosion in North Sea Oil and Gas Pipelines. This study will involve electrochemical and metallurgical study of crack propagation mechanism in stressed pipelines as well as computer simulation of mass transfer effects at the crack tip. The work will be done in collaboration with the British Petroleum Research Centre, Sunbury-on-Thames.

Candidates should have a good honours degree in Chemistry, Materials Science, Chemical Engineering or any other related discipline. The awards will be at the S.R.C. research studentship rate plus industrial allowance.

Applications, together with the names of two referees should be sent to Dr A. C. C. Tseung, Department of Chemistry, The City University, Northampton Square, London EC1V 0HB. 2182(F)

## THE POLYTECHNIC OF NORTH LONDON

DEPARTMENT OF

MATHEMATICS

### S.R.C. C.A.S.E. STUDENTSHIP

### IN THEORETICAL

### AERODYNAMICS

Applications are invited for a collaborative research studentship jointly sponsored by the Science Research Council and Rolls-Royce Ltd. The project involves mathematical modelling of the aerodynamic design of turbomachinery components under mechanical constraints.

Applicants should hold, or expect to obtain this year, a good honours degree in Mathematics, or another suitable subject, and satisfy the usual S.R.C. requirements. The successful applicant will be expected to register for the M.Phil./Ph.D. degree of the C.N.A.A.

During the three years of the project the selected candidate will be based at the Polytechnic, but will, normally, be offered employment by Rolls-Royce Ltd, from October 1979 at full salary commensurate with age and qualifications.

Further details and application forms can be obtained from the Head of the Department of Mathematics, The Polytechnic of North London, Holloway, London N7 8DB. 2181(F)

## UNIVERSITY COLLEGE LONDON

DEPARTMENT OF

GEOLOGY

### C.A.S.E. STUDENTSHIP

Applications are invited for N.E.R.C.-funded C.A.S.E. Studentships to be undertaken in conjunction with the Institute of Geological Science. The successful applicant will study known Rare Earth Element and Lead anomalies in soils and stream sediments of mid-Wales in order to establish the chemical processes responsible for their formation. The project is suitable for persons qualified in either geology or chemistry. Applications should be sent to Dr J. N. McArthur, Department of Geology, University College London, Gower Street, London WC1E 6BT from whom further particulars may be obtained. 2193(F)

## AGRICULTURAL RESEARCH COUNCIL

### STUDENTSHIP

at the WEED RESEARCH

### ORGANIZATION

There is a Postgraduate Studentship available at WRO to enable honours graduates to study for a higher degree.

The project to be researched concerned with the incidence, mechanism and importance of vegetative regeneration in grassland.

For further particulars and a application form write to Secretary Weed Research Organization, Be broke Hill, Yarnton, Oxford OX5 1PF, quoting 16/79. Closing date June 30, 1979. 2218(F)

## UNIVERSITY OF LONDON KING'S COLLEGE

### S.R.C. C.A.S.E. STUDENTSHIP

Applications are invited from British graduates holding a First or Upper Second Class Honours degree in Biochemistry or Pharmacology, or from British students expecting to obtain such a degree this summer, to pursue research on tachyphylaxis in human blood platelets and its relevance to the control of platelet responsiveness. The studentship is held in association with CIBA-Geigy (U.K.) Ltd.

Applications should be sent, as soon as possible to Professor M. C. Scrutton, Department of Biochemistry, King's College, Strand, London WC2R 2L. 2263(F)

## FELLOWSHIPS

UNIVERSITY OF  
ABERDEENRESEARCH FELLOWSHIP OR  
RESEARCH ASSISTANTSHIP  
IN BIOCHEMISTRY

Applications are invited for a Postdoctoral Research Fellowship with Dr J. E. Fothergill's research group, to determine the structure of the serine proteinase chain of CIs, the enzymically active part of the first component of complement.

The appointment for up to 3 years is supported by the MRC; starting date by arrangement. Salary within Range 1A, £4,232 to £5,321 (under review) with appropriate placing.

Predocutorial appointments with suitable interests and experience will also be considered as Research Assistants (salary as above but within Range 1B).

Further particulars from The Secretary, The University, Aberdeen, with whom applications should be lodged as soon as possible but not later than September 1, 1979.

2204(E)

## ROTHMANS FELLOWSHIPS

Applications are invited for Rothmans Fellowships, which are awarded under the Rothmans University Endowment Fund set up by Rothmans of Pall Mall (Australia) Limited to enable Fellows to undertake postgraduate work within an Australian University.

Rothmans Fellowships are of an annual value of up to \$A14,000. A Fellow may be paid travelling expenses incurred in taking up the Fellowship and returning home.

In addition, an amount of \$A1,500 per annum towards fees and expenses including the purchase and maintenance of equipment may be paid to the University where the Fellow is working.

A Fellow shall take up a Fellowship before attaining the age of twenty-eight. The Fellowships are open to graduates of any University who have had at least three years postgraduate experience in research. The Fellowships are not open to permanent members of academic staff or applicants proceeding on sabbatical, study or other leave (including leave without pay). The Fellowships must be held at an Australian University.

Application forms and further details may be obtained from the Secretary, Rothmans University Endowment Fund, C/- The University of Sydney, NSW 2006, Australia. Applications close on September 28, 1979. Information also available from Association of Commonwealth Universities (Apts), 36 Gordon Square, London WC1H 0PF. 2188(E)

UNIVERSITY OF DUBLIN  
Trinity College

A Postdoctoral Fellowship, supported by the National Board for Science and Technology, is offered for two years from October 1, 1979. The project, on ion-containing polymers, is jointly directed by J. V. McBrierty and J. M. D. Coey. It exploits the NMR and Mossbauer techniques to provide molecular information on this rapidly developing class of polymeric materials. Direct experience in some branch of magnetic resonance on Mossbauer spectroscopy would be an advantage.

Salary will be in the range £3,837 to £4,476.

Interested persons should, in the first instance, telephone the Staff Office, Trinity College, on Dublin 772941, Ext. 1678 or Ext. 1775.

The closing date for receipt of completed applications will be July 15, 1979. 2241(E)

RESEARCH FELLOWSHIP  
IMPERIAL CANCER  
RESEARCH FUND

We have a vacancy for a postdoctoral Research Fellow to join a group working on ageing and neoplastic transformation in epithelial cell systems *in vitro*. Special experience in cell culture techniques, cell hybridisation, etc., an advantage.

Appointment will be for three years. Salary according to qualifications and experience.

Further information from Dr L. M. Franks (01-242 0200, ext. 211). Applications with curriculum vitae and names of two referees should be sent to The Secretary, Imperial Cancer Research Fund, Lincoln's Inn Fields, London WC2A 3PX. 2250(E)

## UNIVERSITY OF BRISTOL

VETERINARY  
RESEARCH FELLOWSHIP

Applications are invited from veterinary graduates for a Research Fellowship to investigate the physiology of cervical dilatation in the ewe. The successful applicant will join a research group in the Department of Anatomy which is currently working on problems of the myometrium and the physiology of relaxin. The group has accommodation for sheep at Bristol and at the School of Veterinary Science, Langford. It is intended that the applicant will employ a variety of research techniques in the elucidation of this problem, including chronic recording of cervical softening *in vivo*. The opportunity exists to investigate the histochemistry of the glycosaminoglycans of the cervix. In addition, the Department offers a wide spectrum of facilities and expertise in electron-microscopy, electro-physiology, polypeptide biochemistry, neurophysiology, hard tissue studies, and experimental surgery.

The Fellowship is provided by the Agricultural Research Council and awards a salary of £4,232 to £8,452 depending upon age and experience. The appointee will be expected to register for a higher degree.

Applications in duplicate which should include a full curriculum vitae together with the names and addresses of two referees should be sent to Professor D. G. Porter, Pre-Clinical Veterinary Studies, Department of Anatomy, The Medical School, University of Bristol, Bristol BS8 1TD. 2248(E)

IMPERIAL CANCER  
RESEARCH FUND  
RESEARCH FELLOWSHIP

A Postdoctoral Biochemist or Molecular biologist with experience in DNA sequencing techniques is required to assist in cloning and to sequence biologically significant regions of higher eukaryotic DNA.

The appointment will be for three years. Salary range £5,823 to £7,129 inc. L.A.

For further information telephone Dr M. Fried (01-242 0200, ext. 297). Applications with curriculum vitae and the names of two referees should be sent to the Secretary, Imperial Cancer Research Fund, Lincoln's Inn Fields, London WC2, quoting Reference 302/79, by July 30, 1979. 2251(E)

UNIVERSITY OF DUNDEE  
POSTDOCTORAL  
BIOCHEMIST

Applications are invited for a S.R.C. grant-financed postdoctoral fellowship to work in collaboration with Dr D. G. Nicholls on a project whose aim is to establish the molecular mechanism by which noradrenaline regulates the exothermic metabolism of isolated brown adipose cells. For reviews see Biochem. Soc. Trans. 5 (1977) 908; New Scientist, April 13, 1978. The Neurochemistry Laboratory is located in the Department of Psychiatry, and has close ties with the Department of Biochemistry.

The post is available from October 1, 1979, but later starting dates would be considered. The appointment is for up to two years.

Salary within the range £4,232 to £4,776.

Informal enquiries may be made to Dr D. G. Nicholls, Neurochemistry Laboratory, Department of Psychiatry, Ninewells Medical School, University of Dundee. Applications, quoting reference EST/61/79J and containing the names of two referees should be lodged with The Secretary, The University, Dundee DD1 4HN as soon as possible. 2197(E)

UNIVERSITY OF SUSSEX  
SCHOOL OF  
BIOLOGICAL SCIENCES  
POSTDOCTORAL  
RESEARCH FELLOWSHIP  
MOLLUSCAN  
NEUROBIOLOGY

To work on an M.R.C.-financed project investigating the regeneration of specific neural connections in the snail brain. Experience in intracellular recording required, together with an interest in developmental neurobiology. Appointment will be for 18 months in the first instance, with extension dependent on the availability of further finance.

Salary within range £4,232 to £6,627 per annum on the Research Fellow grade 1A scale (under review). Applications, detailing c.v. and the names of two referees, as soon as possible to Dr P. R. Benjamin, School of Biological Sciences, University of Sussex, Falmer, Brighton BN1 9QG. 2183(E)

THE UNIVERSITY  
OF LEEDSDEPARTMENT OF METALLURGY  
RESEARCH FELLOWSHIP IN  
ELECTRON MICROSCOPY

Applications from suitably qualified candidates are invited for a temporary post of postdoctoral Research Fellow in the above department to assist in the application of high-resolution electron microscopy and microanalysis to a variety of problems in Metallurgy and Materials Science. A JEOL J20CX TEMSCAN system will be used. Applicants should have considerable experience in electron microscopy, ideally but not necessarily in the use of lattice-imaging techniques, STEM or electron probe microanalysis. The appointment will be made for a fixed period terminating on June 30, 1982.

Starting salary in the range £4,333 to £5,777 on the 1A scale for Research and Analogous Staff (£4,333 to £7,521). The scale quoted is effective from October 1, 1979 and is subject to review.

Applications, with curriculum vitae and the names of two referees, should be sent to the Registrar, The University of Leeds, Leeds LS2 9JT (from whom further particulars may be obtained) not later than July 10, 1979. Please quote reference number 70/4/D. 2171(E)

MASSEY UNIVERSITY  
Palmerston North, New Zealand  
DEPARTMENT OF  
MICROBIOLOGY  
AND GENETICS  
POSTDOCTORAL  
RESEARCH FELLOWSHIP

Applications are invited for a postdoctoral fellowship to study DNA homology among legume root nodule bacteria and its relationship to plant specificity. Applicants should have a background in microbiology or biochemistry. Experience in microbial genetics and nucleic acid biochemistry would be an advantage.

The post is available for three years at an initial salary of NZ\$8,500 per annum. Applicants should indicate the earliest date on which they could be available.

Further details of the position can be obtained from Dr B. D. W. Jarvis, Department of Microbiology and Genetics, Massey University.

Details regarding conditions of appointment and of the University may be obtained from the Association of Commonwealth Universities (Apts), 36 Gordon Square, London WC1H 0PF, or the Registrar of the University.

Applications close July 13, 1979. 2189(E)

WEIZMANN INSTITUTE OF  
SCIENCE FELLOWSHIP

For Researchers with Ph.D. and training in plant physiology, biochemistry and cell biology to participate in a project on aspects of selection for pesticide resistance and pesticide metabolism and physiology in cell cultures. One year with possibility of renewal up to three years.

Send curriculum vitae and names of two referees with request for further information to:

Dr J. Gressel,  
Plant Genetics Department,  
Weizmann Institute of Science,  
Rehovot,  
Israel. W177(A)

## GRANTS &amp; SCHOLARSHIPS

UNIVERSITY OF SYDNEY  
THE THOMAS LAWRENCE  
PAWLETT SCHOLARSHIP

Applications are invited from graduates of universities outside Australia who propose to undertake postgraduate study in the Faculty of Agriculture. The scholarship, which is valued at \$A4,200 per annum, is tenable for one year, but may be renewed.

Further information and application forms may be obtained from the Registrar, University of Sydney, NSW 2006, Australia, with whom applications close on July 31, 1979. 2185(H)

THE ROYAL SOCIETY  
GOVERNMENT GRANT  
for Scientific Investigations

Application for grants from the second allotment of the Government Grant for Scientific Investigations for the year 1979 should be made not later than July 15, 1979 on forms of application to be obtained from the Executive Secretary of the Royal Society, 6 Carlton House Terrace, London SW1Y 5AG.

Applicants must be British subjects domiciled in the United Kingdom. Grants may be made to promote and support research in science and to assist scientific expeditions and collections; but not for personal maintenance, payment of stipends or to aid scientific publications. 2179(H)

## GRANTS & SCHOLARSHIPS —continued—

### UNIVERSITY OF SUSSEX

#### MARGARET GRANT MEMORIAL SCHOLARSHIP

Applications are invited from young scientists for the first annual award of this fellowship established to promote the communication of ideas and techniques among cell biologists, biochemists and microbiologists from all countries. Preference will be given to applicants at an early stage of her/his career. The award is to support visits to other laboratories to learn techniques or extend collaborative experiments. Awards will be in the region of £150 to £300 to help with travel and living expenses. Apply in detail to Professor S. Shall, Biochemistry Department, School of Biological Sciences, University of Sussex, Falmer, Brighton BN1 9QG. Deadline: August 1, 1979. 2184(HH).

## ASSOCIATESHIPS

### UNIVERSITY OF BIRMINGHAM DEPARTMENT OF BIOCHEMISTRY A RESEARCH ASSOCIATESHIP

is available to assist in the production of monoclonal antibodies to muscle proteins for the study of the origins and diagnosis of muscle disease (supported by a grant from the Muscular Dystrophy Group of Great Britain to Professor S. V. Perry). Salary on the scale £3,775 to £4,333 (plus U.S.S.). (Ref. BS1).

#### A RESEARCH ASSOCIATESHIP

is being funded by the University of Birmingham to develop facilities for the culture of hepatocytes and the monoclonal production of antibodies to enzymes. Salary on the scale £3,775 to £5,488 (plus U.S.S.). (Ref. BS2).

Both posts are tenable from October 1, 1979. Postgraduate experience in tissue culture techniques would be an advantage for both posts. The Muscular Dystrophy funded post is available initially for one year but with the possibility of an extension for a further two years depending on availability of funds. The university funded post is for three years.

Further details may be obtained from Miss L. R. Hayes, Senate Registry, University of Birmingham, P.O. Box 363, Birmingham B15 2TT, to whom applications (two copies) should be returned not later than Friday, July 6, 1979. Please quote reference number of post in any enquiry. 2209(O)

### UNIVERSITY OF BIRMINGHAM DEPARTMENT OF BIOCHEMISTRY A RESEARCH ASSOCIATESHIP

is available from October 1, 1979, to evaluate the application of high resolution two dimensional electrophoresis of the protein and other components of human body fluids and tissues in the diagnosis and study of the origins of neuromuscular diseases.

The appointment is supported by a grant from the Muscular Dystrophy Group of Great Britain to Professor S. V. Perry, and is initially for one year but with the possibility of an extension for a further two years depending on the availability of funds.

Salary in the range £3,775 to £4,333 (plus U.S.S.) depending on age and qualifications.

Further details may be obtained from Miss L. R. Hayes, Senate Registry, University of Birmingham, P.O. Box 363, Birmingham B15 2TT, to whom applications (two copies) should be returned not later than Friday, July 6, 1979. 2210(O)

## AWARDS

### UNIVERSITY OF LEICESTER DEPARTMENT OF CHEMISTRY S.R.C. C.A.S.E. AWARDS

Applications are invited from graduates (or potential graduates) with a degree with First or Second Class Honours (Upper Division) in Chemistry, or equivalent qualifications, for the following S.R.C. C.A.S.E. awards:

1. "ESR Studies of Organo-halide Radicals" in collaboration with I.C.I. (Mond Division); and under the direction of Professor M. C. R. Symons.
2. "Kinetics and Mechanism of Pyrolysis of Silacycloalkanes" in collaboration with Dow Corning; and under the direction of Dr I. M. T. Davidson.
3. "Preparation and Thermodynamic Properties of Actinide Mixed Oxides", in collaboration with A.E.R.E. Harwell; and under the direction of Dr J. H. Holloway.
4. "Chemistry of Actinide Pentafluorides and Related Compounds" in collaboration with A.E.R.E. Harwell; and under the direction of Dr J. H. Holloway.
5. "Uses of Fragmentations of Cyclic Sulphones in Synthesis" in collaboration with Oxford Chemicals and under the direction of Dr D. J. H. Smith.

Full details and application forms may be obtained from the appropriate directors at the Department of Chemistry, University of Leicester, LE1 7RH. 2231(N)

## ASSISTANTSHIPS

### IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY DEPARTMENT OF BIOCHEMISTRY

#### POSTGRADUATE RESEARCH ASSISTANTSHIP

A Postgraduate Research Assistant is required to work with an active research group studying pancreatic endocrine function in experimental obesity. The position will be available from mid-July. Previous experience would be welcomed but is not essential.

The starting salary will be within the range £3,718 to £5,333 per annum (according to age and experience) plus £502 London Allowance and U.S.S. benefits.

Applications, including a curriculum vitae and the names of two referees, should be sent, as soon as possible, to Dr Anne Beloff-Chain, Department of Biochemistry, Imperial College, London SW7 2AZ. 2132(A)

### THE UNIVERSITY OF SHEFFIELD DEPARTMENT OF METALLURGY POSTDOCTORAL RESEARCH ASSISTANTSHIP (S.R.C.)

Applications invited from men and women scientists and engineers for a vacancy in an interdisciplinary team working on evaporation and fuming of metals. Experience of laser applications desirable but not essential. Tenable to June 30, 1981. Salary up to £4,776 a year (under review) with superannuation. Write to Dr E. R. Buckle, Department of Metallurgy, The University, Sheffield S1 3JD. Quote ref. R317/G. 2172(P)

### UNIVERSITY OF DUNDEE

#### DEPARTMENT OF MATHEMATICS

Applications are invited for a

#### POSTDOCTORAL

#### RESEARCH ASSISTANTSHIP

to work with Dr D. F. Griffiths in the above Department on finite element methods in fluid dynamics. The appointment will be available for two years from September 1, 1979 at a starting salary in the range £4,232 to £4,776 (under review) depending on age and qualifications.

Applications, which should include a curriculum vitae and the names and addresses of two referees, should be sent as soon as possible to The Secretary, The University, Dundee DD1 4HN, from whom further particulars may be obtained. Please quote reference EST/18/79J. 2196(P)

### UNIVERSITY OF BRISTOL

#### Department of Physics

Postdoctoral Research Assistantships, S.R.C. funded, are available in specific areas of polymer science relating to crystallization, structure and properties. Basic background in one of the physical sciences essential with some experience in the polymer field and/or structure techniques.

Applications to be addressed to Professor A. Keller, H. H. Wills Physics Laboratory, University of Bristol, Bristol BS8 1TL. 2216(P)

### UNIVERSITY OF OXFORD

#### Inorganic Chemistry Laboratory POSTDOCTORAL RESEARCH ASSISTANTSHIP

Applications are invited for an SRC Research Assistant to study surface chemical reactions using Imaging Atom Probe Field Ion Microscopy. Previous experience in surface chemistry or the use of field electron or field ion emission techniques would be advantageous although of greater importance would be a desire to participate in the development and application of an interesting new technique for surface studies.

The appointment would be for two years in the first instance, preferable from October 1, 1979. The starting salary range would be £4,232 to £4,776.

Applications, accompanied by the names of two referees, should be sent to Dr G. K. L. Cranston, Inorganic Chemistry Laboratory, South Park Road, Oxford, OX1 3QR, from whom further particulars may be obtained. 2230(P)

## COURSES

### EUROPEAN SCIENCE FOUNDATION

#### EUROPEAN TRAINING PROGRAMME IN BRAIN AND BEHAVIOUR RESEARCH

#### E. T. P. WINTERSCHOOL 1980

#### "PAIN"

The E.T.P. Winterschool is a one-week lecture course which is being organised and financed entirely through the European Training Programme in Brain and Behaviour Research. The eighth Winterschool will take place in Zuz (Switzerland) from January 5 to 12, 1980. Lectures and round table discussions will be held on the central topic of "Pain".

The following speakers have been invited: S. Andersson (Göteborg); M. R. Bond (Glasgow); D. Bowsher (Liverpool); G. Carli (Siena); M. von Düring (Bochum); A. Fanchamps (Basel); H. U. Gerbershagen (Mainz); H. Handwerker (Heidelberg); J. van Hees (Leuven); A. Herz (München); A. Iggo (Edinburgh); W. Jänig (Kiel); U. Lindblom (Huddinge); P. W. Nathan (London); P. Procacci (Florence); J. Siegfried (Zürich); A. Struppler (München); L. Terenius (Uppsala); L. Vyklicky (Prague); P. Wall (London); M. Zimmermann (Heidelberg).

The Scientific Organiser of the 1980 Winterschool is Professor R. F. Schmidt (Dept. Physiology, University of Kiel).

The deadline for the submission of completed applications is September 15 and successful applicants will be notified by the end of October. Application forms and further information may be obtained from:

## VECTOR LABORATORIES, INC.

INTRODUCES

### BIOTINYL-LECTINS Biotinyl-ANTIBODY

FOR USE IN THE HIGHLY-SPECIFIC, ULTRA-SENSITIVE

### BIOTIN/AVIDIN SYSTEM

#### A NEW SANDWICH TECHNIQUE

**PRINCIPLE:** Avidin, a 68,000 molecular weight glycoprotein found in eggs, has an extraordinary affinity\* for the small molecular weight vitamin, Biotin. Coupling Biotin to any protein gives that protein the ability to bind Avidin. Avidin conjugated with Ferritin, Fluorescein, Rhodamine or Horseradish Peroxidase can be used to localize Biotinyl-Antibody or Biotinyl-Lectins after they have bound to their receptors.

\*Over one million times higher than most antigen-antibody interactions.

THE BIOTIN/AVIDIN SYSTEM has several advantages over direct coupling of the marker to antibody.

- Improved Sensitivity
- Reduced non-specific binding
- Elimination of steric hindrance problems
- Instantaneous complex formation
- High complex stability
- Simultaneous use of several markers
- Biological processes unaffected
- Wide applicability

#### [BAS] REAGENTS INCLUDE:

Biotinyl-Anti-immunoglobulin antibody  
Biotinyl-Lectins  
Fluorescein-Avidin  
Rhodamine-Avidin  
Horseradish Peroxidase-Avidin  
Ferritin-Avidin  
Agarose-Bound Avidin

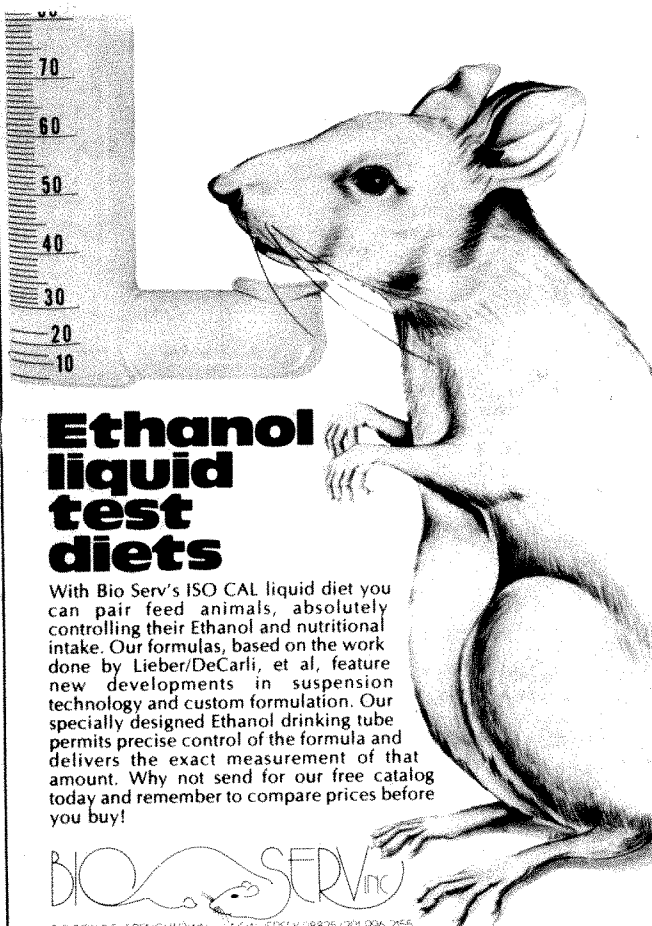

These [BAS] Reagents are available individually or in kit form.

#### INQUIRE ABOUT OUR CUSTOM BIOTINYLATION SERVICE.

Circle No. 03 on Reader Enquiry Card.

**Guide to authors**

● Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.

● Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.

● Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.

● 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

**Manuscripts** may be submitted either to London or New York. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the *Système International*. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; exp (*a*) is preferred to *e*<sup>a</sup> if '*a*' is more than one character.

**References** are indicated by superscripts in the text. See any contemporary *Nature* for style, but note: (i) only one reference number need be used if the reference is to several papers by identical authors. (ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

**Artwork** should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

*Nature's* publishing policy is outlined in 258,1 (1975) and 264, v, 11 Nov. (1976).

## A new approach in tissue culture

### PETRIPERM

a novel culture dish  
with gas permeable  
membrane as cellular  
support.

Additional advantages of the PETRIPERM membrane are:

- UV permeable 200 nm
- Suitable for high power light and fluorescence microscopy
- The membrane can be cut for cell cloning, electron microscopy, staining and documentation
- Chemically resistant to acids, bases and organic solvents

PETRIPERM is available either with a hydrophilic surface for optimal attachment, or with a hydrophobic surface for easy detachment of adherent cells.

In the intact animal, the pH and the partial pressure of both oxygen and CO<sub>2</sub> of the cell environment are under total biochemical and physiological control. This state is not even approximated by available techniques of monolayer cell culture in conventional tissue culture ware. Continuously changing gradients of these parameters in the micro-environment of cultured cells will obscure the biological significance of culture dependent phenomena. PETRIPERM is the prerequisite for the precise control of pO<sub>2</sub>, pCO<sub>2</sub> and pH in the cellular environment as gases reach the cultured cells directly through the highly gas permeable 25 µm thick membrane.

### Heraeus— CO<sub>2</sub>-Incubator B 5060 EK/CO<sub>2</sub>

We build the  
incubator with  
appropriate  
pCO<sub>2</sub>, pH and pO<sub>2</sub>  
control units

## Problems of civil service pay comparisons

Last Friday, many tens of thousands of scientists and technologists, members of the British Civil Service, went on strike for a day. More action — withdrawal of goodwill and selective strikes — is promised by the Institution of Professional Civil Servants (IPCS), which represents about 90% of the civil servants in the relevant categories. For the majority of those who obeyed the strike call, a day away from work probably provided a welcome opportunity to catch up with some reading, secure in the knowledge that the nation's scientific and technological future is hardly put in jeopardy by a day's absence. But IPCS does have muscle; although its officials were at pains to point out that the day was one of protest not disruption, highly visible disruption there certainly was in the area of air traffic control.

Few of those involved in the strike action can have gone as far as this before — what caused the normally moderate and restrained IPCS to use its ultimate weapon? The answer, put simply, is pay, and in particular comparisons between the pay of civil servants and their counterparts outside the service. IPCS negotiates with Civil Service Department (CSD) officials (ultimately with the Minister of State for the Civil Service Department, Mr Paul Channon) over salary. There was a time when the pay for each of the many grades of scientist and technologist was established by a process of 'pay research' — painstaking comparisons were made between industry, commerce, the professions and the Civil Service in order to decide a fair level of remuneration. On the whole these comparisons were based on median salaries outside the Civil Service, but there was one significant exception — the Professional and Technological group of employees, (not the scientists), numbering about 40,000. Traditionally their pay settlements had been at well above the median of outside salaries on the basis that many outsiders, in fields such as architecture and surveying, were in business by themselves and not included in the comparisons, that there were heavy responsibilities and demands of very high quality on civil servants and so on.

Severe pay restraint from 1975 onwards meant an abandonment of pay research at a time when Civil Service salaries looked good — even better if pensions' provisions and stability of employment were allowed for. Since that time there is little doubt that the scientists and technologists in the Civil Service have lost their edge on salaries, and as pay research has gradually come back into action the extent of the increases necessary to bring civil servants back into line has become apparent. The Professional and Technology grade has been offered comparability with the median (raises of between 15% and 22%) rather than comparability with a figure well above the median — CSD rejected IPCS demands that the former grounds for favourable treatment be retained.

It had already been agreed that the Science Group (around 17,000 people) should not go back into pay research comparisons until 1980, and last year CSD declared in writing that it was 'context to accept' IPCS's proposal that for 1979 scientists' pay should be linked to that of administrators. But when administrators got an increase of 25% or more, CSD were unwilling to match the salaries for scientists. It has since done so (on 15 June) but only on condition that future pay for scientists should be based on pay research, even if this should lead to salary reductions next year, and that P & T grades would also abide by pay research (at the median, presumably).

What is behind all this? On the P & T side it is clear that the Government is unconvinced that settlements above the median are now called for, believing that they were based on a small number of special cases. On the Science side, there seem to be unambiguous warnings that the 1980 recommendations from pay research are not going to be very good news; one CSD official commented that there was a possibility that pay research, although not for implementation until 1980, 'might be relevant to the course we should take in 1979'. In other words, brace yourselves for a nasty shock.

There is a real problem here. The heart of the Scientific Civil Service is the two thousand or so Principal Scientific Officers. This is a level up to which many scientists will be moved in their late thirties but out of which relatively few will be promoted. So most PSOs will work at this grade for twenty years or more. Scientists outside the Civil Service are unlikely to be in anything like the same situation, so pay research comparisons at the PSO level (and maybe even just below it) are difficult, to say the least. As a consequence this may lead to depressed salaries.

That scientists and technologists need a pay boost is beyond doubt; the steady trickle of young computer people, for example, out of the service and into industry has to be stopped. But on the other hand salaries which look so good in comparison with industry when that industry is denuded of good people undoubtedly jeopardise Britain's industrial future. So some fine balancing has to be done.

What is in danger of being lost, however, in the heightened temperature of a strike, is the long-term need for a very serious review of the use that the nation should be making of its older scientists. It keeps them in laboratories well beyond the time many of them can (by their own admission) make an adequate contribution; their way into other parts of the Civil Service is barred, despite the benefits that numerate, scientific thinking might bring. As part of any settlement, IPCS and CSD ought to agree to look very carefully at the problem of the Principal Scientific Officer. □

# US seeks to 'rationalise' health and safety regulation in the interest of profits

The role of science in the regulatory process was a central theme in a meeting on science policy held last week by AAAS.

**David Dickson reports**

THE Carter administration is launching a concerted effort to rationalise its environmental and health regulatory mechanisms in a way that will ensure these mechanisms do not sap the vitality of the private sector. According to Mr Bowman Cutter, head of budget affairs in the Office of Management and Budget, the administration's overall aim is "to promote a structure in which decisions [about future investment] can be made rationally."

Precise details of the administration's proposals are expected to be announced shortly. Various alternatives are included among a list of possible decisions now facing President Carter on ways to stimulate industrial innovation, the results of a year-long study by the Department of Commerce.

However the general philosophy of the administration's approach was outlined by three of its principal architects — Mr Cutter, Dr Frank Press, director of the Office of Science and Technology Policy and Dr Jordan Baruch, assistant secretary of commerce — at a meeting on federal research and development policy held last week by the American Association for the Advancement of Science.

From this it emerged that a major emphasis will be placed not on ways in which direct intervention can aid innovation in private firms, but on ways of stabilising and "rationalising" the decision-making environment. And where the Commerce Department's report has provided the rationale, OMB has been studying institutional changes that will help make this possible, and OSTP looking at ways in which science and the scientific community can contribute.

Indeed having done much to set basic research funding on its feet in the first two Carter budgets — Mr Cutter told the AAAS meeting that basic science could expect a further modest amount of real growth in the 1981 budget — the role of science in the regulatory process has now become a central concern to OSTP.

Many companies blame excessive regulation as one reason for the poor performance of the US economy. "Industry has been compelled to spend more and more of its research dollars to comply with environmental, health and safety regulations — and to move away from longer-term efforts aimed at major scientific advances" is a typical complaint from Rawleigh Warne Jr., the chairman of Mobil Oil.

The problem facing the administration is that much of this regulation has been mandated by Congress. It is therefore suggesting, not less regulation as such, but that a distinction be made between necessary and "unnecessary" regulation — a distinction whose validity is questioned by many trade unionists — and that the regulatory burden be rationalised by cutting out the latter.

"Society has made decisions to repurchase clean air and water and to protect the health of workers," Dr Baruch, who was responsible for co-ordinating the Commerce Department study, told the AAAS meeting. "It is imperative that we do not sacrifice the goals of those decisions, but ask how they can be made compatible with the desire to stimulate innovation."

Dr Cutter described the significant impact such regulatory decisions have had on the political landscape. "Prior to the 1960s regulation was largely economic. But subsequently a very new form of regulation has begun to be developed linked to central social objectives," Mr Cutter said.

Similar points were made by Dr Press (in a speech delivered by OSTP associate director Dr Phil Smith), who criticised current regulatory efforts as being "highly-segmented, wide-ranging in impact, economically important, highly politicised, very aggressive, relatively independent, and almost totally uncoordinated."

Specific characteristics, he said, included that existence of distinct regulatory regimes, tough legislative mandates, single priority objectives with less consideration to other impacts (especially costs), the delegation of authority to separate agencies, and "a lack of any mechanism for weighing the overall impact of the sum of the separate programmes."

A major goal of the present administration, which had already implemented various activities to remedy this situation, was "improved care and rationalism, in both substance and process" he said. One area in need of improvement was the uniform application of scientific principles in the regulatory process. Another was the possible use of neutral experts to help "fence in" controversial areas so that debates on regulation "can be confined to legitimate differences in values."

University researchers could play an

"We figured the more regulators there were, the less they'd bother us — and it works!"

important role in these type of fields, he said, for example through campus based research centres. And there was no need for regulatory programmes to inhibit socially desirable innovations.

Both Dr Press and Mr Cutter admitted that rationalising the regulatory process was unlikely to be an easy task. Last year, for example, OMB had brought together seven agencies to compare their various programmes on toxic substances. But Mr Cutter admitted that the results of the exercise had been "not too successful".

This, he said, was partly due to substantial differences in objectives between the various bodies, with regulatory agencies, for example, claiming that the need to fulfil legal mandates was a principal reason for doing research, while basic research agencies gave highest priority to the expansion of knowledge.

"We will have to continue work on this. Research on the impact of regulation must increase; but before we do this, the federal government will have to get its house in order so that we know what we are spending money on and why we are doing it," Mr Cutter said.

Both speakers also agreed that the current position of "social regulation" was similar to that of economic regulation prior to the establishment of OMB by the Budget and Accounting Act of 1921, which for the first time brought the budgets of the various federal agencies together under direct presidential control.

Sceptics point out, however, that this act provided Presidents Harding and Coolidge with both the means and the authority to slash federal spending and keep it down, with total expenditures dropping from \$5.1 billion in 1921 to \$3.4 billion in 1922, and remaining low until the end of the decade. They are hoping that history will not repeat itself too closely.

## Carter aims at 20% solar energy

PRESIDENT Carter last week unveiled a package of proposed legislative measures designed, he said, towards meeting a national goal of 20% of US energy needs coming from solar and renewable resources by the end of the century.

Among the proposals are the setting up of a \$100 million solar energy bank to subsidize the interest on loans and mortgages made to home-owners and businessmen to install solar energy devices; extensive tax credits for solar installations; and the shift in emphasis from demonstration programmes of high-cost centralised solar electric technologies to "those systems which hold wider potential to displace the use of oil and natural gas".

As a result of these new programmes, the total commitment of the federal government in 1980 to solar energy will be more than \$1 billion, "a significant milestone for our country", the President said in a message to the Congress listing his proposals.

However the President's decision to fund some of the developments, including in particular the solar energy bank, from a tax he is proposing on the "windfall profits" expected by oil companies as a result of recent price increases, has been attacked by environmentalists as a political move to gather support for the proposed tax, and thus putting the solar efforts in jeopardy.

In deciding on an ambitious target of 20% solar energy by 2000 — of which one third may come from solar heating, one third from solar cells, and the rest from sources such as hydropower, windpower and the conversion of waste products into energy — the President had had presented to him a range of options, some of which placed the target much higher.

But Dennis Hayes, a research fellow at the Worldwatch Institute in Washington and a leading advocate of solar power, told a House subcommittee the previous week that the cost of the higher options, which administration officials had estimated to cost \$113 billion to reach a solar contribution of one-third of the US energy needs by 2000, had been substantially overestimated, and that in an era of fiscal frugality the high estimate had been a "kiss of death" to more ambitious plans.

The main proposals in the President's programme are:

- a 20% tax credit up to \$2,000 on new houses built to maximise the use of the sun's energy through "passive" designs
- a tax credit for commercial and multi family buildings of \$20 per million Btu saved beyond energy standards for large buildings
- increasing from 10 to 25% the tax credit for solar equipment designed to provide heat for industrial and

agricultural purposes such as drying crops

- a 15% tax credit for the purchase and installation of air-tight woodburning stoves in principal residences

- a permanent exemption from the 4-cents-a-gallon federal gasoline tax on gasohol, a mixture of 90% gasoline and 10% alcohol.

The response of environmentalist groups to the President's proposal however has been little more than lukewarm. Many of his suggestions, they point out, are already being pursued by individual legislators, while linking the solar bank to the energy trust fund, itself a highly controversial proposal in Congress, is, they claim, an unnecessarily risky move.

Many also doubt whether the amount of money which the President proposes to spend on solar energy is sufficient to head toward the goal by 2000 that he has set the nation, especially when compared to the amount of money that continues to be spent on the development of other energy resources such as nuclear energy.

"The proposed programme is a big disappointment to us; the President is talking about a minimal 5% spending on solar energy compared to other energy sources to reach an ambitious 20% goal," said Herb Epstein of the Solar Lobby, adding that his and other groups would seek to have the financial support and tax credits substantially increased as the proposals passed through Congress. □

Here comes the sun: research on solar cells using a fresnel lens at the Sandia Laboratory

## Senate vetoes plan for Third World research agency

CONSERVATIVES in the US Senate, quoting the need to restrain both public spending and the growth of the federal bureaucracy, have rejected President Carter's proposal to establish a new institute for scientific and technological research related to the needs of developing countries.

The Senate's action is not necessarily fatal to the plans for the institute, provisionally known as the Institute for Scientific and Technical Cooperation (ISTC). The House of Representatives last month defeated a similar move to kill the institute; and the legislation establishing it may therefore well be restored when Senate and House conferees meet next week to resolve differences before the relevant parts of the foreign aid bill become law.

However the Senate's decision took many of the institute's supporters by surprise, being described in terms ranging from "shock" to "disaster". "The decision is certainly very disappointing, and has effectively derailed the ISTC at the present time, although we hope that it will not turn out to be decisive," Dr Ralph Smuckler, head of the institute's planning office, told *Nature* last week.

One effect has been to cast a shadow over US preparations for the United Nations Conference on Science and Technology for Development, at which ISTC is planned to be a centrepiece in the US presentation. There is some concern that, in an attempt to appease the critics, the administration might be tempted to water down the proposal and tie it more closely to existing programmes and agencies — a move which, some fear, could seriously diminish the credibility of the institute in the eyes of many Third World countries.

It has largely been in response to inadequacies in current aid programmes that the idea of an institute specifically devoted to scientific research on Third World issues has been discussed in Washington and elsewhere since the mid-1960s, most recently in a report from the Brookings Institute.

Following these discussions, President Carter announced in a speech in Venezuela last March that he was proposing setting up a new institute with two main aims: to focus scientific effort on specific problems facing Third World countries, in areas such as health, medicine and agriculture, as well as "global" problems such as energy and the environment; and to assist developing countries in establishing their own research capabilities as a necessary step towards modernisation.

The principle of working towards these

two objectives has received wide support from virtually every sector of the US scientific and political community. The main point of dispute, however, has been over appropriate procedures, and specifically the extent to which such activities should be tied to the policy directions of other institutions.

The administration has argued publicly that although ISTC will be conceived as part of an overall development assistance strategy, the existence of a council of advisers to the ISTC's director will provide sufficient autonomy; and, privately, that anything giving greater Third World involvement in decision-making — along the lines, for example, of Canada's International Development Research Center — would fail to gain Congressional support.

During last week's debate, the Senate rejected an amendment proposed by Senator Adlai Stevenson to increase the institute's autonomy by making the directors responsible to a board of directors. Although this proposal has been widely supported in the academic community, the administration claimed that it would weaken the links to other development efforts.

Supporters of the bill had spent considerable time putting their case against the Stevenson proposal. In doing so, it turned out that they had paid insufficient attention to the threat from the other direction, namely a growing conservative constituency in the Congress pledged to cut public expenditure and the federal bureaucracy.

These were the forces that provided support for an amendment from Senator Dennis Deoncini, a Democrat from Arizona, proposing that the legislation setting up the proposed ISTC be removed entirely from the International Development Assistance Act for 1980.

"At a time when the American people are themselves struggling to make ends meet, because of spiralling inflation and the beginnings of what promises to be a substantial recession, we can ill afford another well-intentioned but expensive agency to study and coordinate the problems which are all too depressingly familiar," Senator Deoncini said.

Although the funding requests associated with the institute were not great — the administration is initially asking for an additional \$25 million to support the institute's activities in the first year, most of its budget resulting from the transfer of research projects under way in the Agency for International Development (AID) — it would subsequently devour tax dollars at an ever-increasing rate, he said. If the new agency was a response to shortcomings in AID, then improvements should be made in AID, rather than creating a "whole new bureaucracy".

Senator Deoncini was joined by Senator Robert Dole of Kansas, who referred to reports appearing in the

national press that the United Nations currently holds a substantial amount of operating funds in low-interest bank deposits. "We do not need to solve another social problem by throwing more money at it — particularly at a time when similarly destined money is presently being wasted," he said.

Supporters of the administration proposal replied to such charges by claiming that the ISTC would considerably increase the effectiveness of US aid efforts, but in the end their arguments failed to carry sufficient weight; and the amendment rejecting the institute from the aid bill was agreed by 58 votes to 42 — a margin which is said to have taken even the amendment's supporters by surprise.

"It was essentially a conservative vote, with people in the middle whose support we had previously been counting upon

arguing that the line on spending had to be drawn somewhere, and choosing this as the issue on which to do it," one administration official told *Nature* last week.

The precise fate of ISTC will not be known until representatives of the House and the Senate meet in the near future to negotiate over their differences on the foreign aid bill, in order to come up with a form that will be acceptable to both sides and can therefore be signed into law. The hope is that the conferees will agree to keep the institute in, possibly in return for cuts elsewhere.

But the restoration of funds is by no means certain. As one Washington lobbyist said last week: "Congress seems to have gone crazy this year in its desire to cut the budget; and the things that are easiest to cut are the things that are related to overseas." □

*Mutual applause: Carter and Brezhnev after the SALT treaty*

## SALT warning on MX missiles decision

ALTHOUGH urging support for the Strategic Arms Limitation Treaty recently signed by President Carter and President Brezhnev in Vienna, the Arms Control Association has warned that the benefits of the treaty will be undermined by the administration's decision to proceed with research and testing of a new generation of mobile missiles, known as MX.

In a statement released last week in Washington, the board of directors of the association say that, despite the closing of US intelligence bases in Iran, it considers the SALT II treaty to be adequately verifiable — a central issue of debate in the US Senate — and urges its ratification without substantive change.

However the ACA also expresses concern at the implications of the administration's recently announced plans to proceed with the design, development and deployment of the new MX missiles — possibly housed in and launched from underground trenches or

from holes on a "shell-game" principle — as a response to the increasing accuracy of Soviet weapons.

Criticising the lack of controls over increasing accuracy of ICBMs the ACA also says that "Deployment of more land-based, silo-destroying missiles will threaten nuclear stability and erode the basis of SALT still further if they are emplaced in mobile basing modes which multiply potential targets, forcing an adversary to programme additional warheads for targets which, in fact, contain no missiles."

The statement says that the problem of silo vulnerability is "largely hypothetical from an operational standpoint", and argues that deployment of the MX and similar systems by the USSR "will pose a far greater danger to American security, and to the SALT process and its accomplishments, than does the current prospect of a hypothetical Soviet attack on American land-based missiles." □

# Rickets under control again in UK

VITAMIN D deficiency rickets is not a disease of epidemic proportion in Britain's Asian community. Dr John Ablett, a senior medical officer in the Department of Health and Social Security (DHSS), said last week there was now enough evidence to confirm that rickets is again on the decline in the UK. The DHSS now takes the view that rickets can be eradicated completely by the use of direct vitamin D supplements to children at risk. A policy of fortifying specific target foods — such as chapati flour — is therefore not necessary.

Rickets was first documented as a serious problem in the Asian community of Glasgow 18 years ago, and since then it has been observed in most of the larger Asian communities in the UK. Despite claims to the contrary by some doctors, the DHSS says the problem can be controlled by the traditional method of vitamin D supplements backed up by a health education programme — directed at the Asian community — about rickets and its adult equivalent, osteomalacia.

The claim that rickets is on the decline is based on figures from hospital admission records. Rickets is not a notifiable disease and data collection is not easy. However, the DHSS has used figures from its Hospital Inpatient Enquiry programme — in which 10% of all hospital admissions are analysed — from over 90 areas. The declining national trend, says the DHSS, is also supported by a survey involving general practitioners in areas with a large immigrant population.

The DHSS says there is evidence that Asian immigrants are entering the country with rickets or osteomalacia, which are quite common in India, Pakistan and Uganda. This means it should now be possible to identify the population most at risk. According to Ablett, the high risk are the infant children of recent immigrants who may be vegetarians, who come from a poor rural background, and who may have a family history of rickets and osteomalacia.

The DHSS's decision that it does not want a food fortification programme is in line with the recommendation of the department's Committee on Medical Aspects of Food Policy (COMA), which has studied the problem for three years.

The composition of milk cannot be altered without renegotiations of a European Economic Community directive (see *Nature* 270, 289; 1977). Margarine has a high composition of fatty acids (46% in some brands; butter has only 10% trans fatty acids) and is causing concern to DHSS officials anyway, as these acids have been implicated in some forms of cancer.

Chapati flour, the most serious conten-

One of the healthy ones: a hospital survey showed decline in rickets in immigrant areas

der, also has problems, largely over what concentration of vitamin D to use. A concentration sufficient to prevent rickets in young children would be dangerously high for adults consuming more flour per head. This is too risky, the DHSS argues, as there is now evidence to suggest that high vitamin D intakes result in high blood calcium and may cause cardiovascular complaints and even heart attacks.

The other problem with vitamin D in chapati flour is that the vitamin is unstable, and up to 50% may be broken down in cooking processes. These technical problems with the flour have still not been resolved, and millers are reluctant to embark on a vitamin D fortification programme unless forced to do so by law.

Finally, there is the problem of hypercalcaemia. The DHSS believes — and the COMA report due to be published next year will say this — that there is now good evidence to show that high vitamin D intakes in the 1950s caused the deaths of over 200 infants reported to have hypercalcaemia. Although the DHSS acknowledges that chapati flour fortified with vitamin D would not affect this age group, it says that high vitamin D intakes could cause problems for older teenagers and young adults.

In reaching its conclusion to rely on vitamin D supplements, COMA will point out that cod liver oil supplements reduced the incidence of rickets in children, from 13% in 1943 to almost nil by the end of the Second World War in 1945. If vitamin D supplements could eradicate the problem then, the DHSS argues, that it could do the same today.

However, there may be problems on the way. Preliminary evidence from Glasgow and Birmingham suggests that some 10% of children receiving vitamin D supplements are still developing rickets. These groups will require closer scrutiny to identify why this is happening.

Alastair Hay

## UK scientists wait anxiously for £7.5m share-out

SCIENTISTS throughout Britain will learn in the next two or three weeks if they have earned a share in the Science Research Council's £7.5 million special investment in new equipment for university and polytechnic research departments. The cash distribution, which will benefit several hundred projects, follows the last government's improvements in the science budget and although the present administration has since reduced the level of increase, the SRC is committed to the move.

Originally only about £3 million had been considered for the equipment programme but the SRC has since been inundated with responses from scientists following its March appeal for applications for new research hardware. Now an expected £5.25 million alone is to go to chemistry, physics, biology and other departments covered by the SRC's science board and the remaining £2.25 million will be split between departments covered by the engineering, astronomy, and nuclear physics boards.

The decision to invest its share of the first £10 million increment in the science vote on equipment follows the SRC's prophetically accurate view that future increases were by no means guaranteed. So it was decided to spend the money as quickly as possible and grants for projects which would involve commitments to staff for several years were ruled out.

"We consider the best way that we can help universities and polytechnics to benefit from the present circumstances is to encourage them to pay particular attention to their needs for equipment", stated the March letter from the SRC to researchers.

This decision also recognised that many departments are facing severe financial problems in purchasing modern, sophisticated — and expensive — replacements for outdated instruments to provide the traditional "well-founded" university laboratory. This latter role is the function of the University Grants Committee, of course, but there are many intermediate areas between the domains of the SRC and the UGC.

Although the SRC stresses that it is not taking over any of the UGC's functioning, it is hard not to view the move as some form of help for the now financially-burdened UGC. However, in providing this new equipment, which will include items such as nuclear magnetic resonance instruments and mini-computers, the SRC is selecting those laboratories where it feels investment is best suited for its future research programme.

And the level of this need for new equipment can be judged by one estimate of £35 million for the total value of the applications received by the SRC. However

these applications were dealt with by the usual grant selection committees of the SRC and only those graded "alpha" were considered for equipment grants. Of these, about 50 per cent were selected for awards.

Now researchers are about to learn if their projects have been judged suitable.

Robin McKie

## Investors refuse to back genetic engineering

ALTHOUGH two major British firms are investing in the industrial application of genetic manipulation techniques, some academics feel the UK is not putting enough money into transferring their research work into industry. The UK has not managed to adopt the US practice of using venture capital to set up small groups of academics and industrialists who develop research to the point where it can be applied to industrial processes. "Investment in the UK is very low", according to Professor K. Murray of Edinburgh University. "Most of the use of genetic manipulation is by small US venture capital groups."

At a meeting on "new horizons in industrial microbiology" at the Royal Society last week, several industrialists responded to these criticisms by saying that venture capital was available but that "research has to pay at some time". The economic climate in the UK meant that many firms did not think it was worth taking the risk of backing a new and uncertain technology. Even if the manufacture of drugs and vaccines by genetic manipulation and, more generally, the production of alternative fuels from organic material by microbiological methods, did become technically feasible, it would be some time before the new processes were economically competitive with current technologies.

A lack of communication between academics and industry was partly to blame for the failure to transfer new ideas. Academics tended to approach industry before their research was sufficiently developed for industry to take advantage of it. Industry, on the other hand, was not willing to take up a promising piece of research where the academics had left off. The result was a gap where good research could fall by the wayside. Dr J D Coombes of Hoechst, UK thought that matters might be improved if academics did not always have to approach the National Research Development Corporation first with their ideas and if they could hold patents.

For the scientists, a major worry was that government spending cuts might affect research. "Staff levels are running down and capital expenditure is down. We will not be able to conserve the strength we already have," said Professor B S Hartley of Imperial College. □

Poznan Fair: only the Poles had their own trading agency

## Selling Polish science

THIS year, for the first time, the Polish Ministry of Science, Higher Education and Technology is appearing as an exhibitor in its own right at the Poznan International Fair, under the trading name Posteor; previously only projects developed in universities and polytechnics under its aegis have been on display.

Posteor is a financially autonomous organ of the Ministry of Science, somewhat analogous to the UK National Research Development Corporation. It was set up in 1973, a time when the Academy of Sciences first scrutinised the problems involved in the relationship between research and production. These discussions led to Poland's scheme of graduated 'problems' vital to the economy which are to be solved by science (23 November 1978 page 313); while, on the administrative side, Posteor was established to handle the implementation of new discoveries and technologies into production.

Implementation is a major problem throughout the Comecon bloc, but only Poland has adopted the idea of a special trading company. Indeed, by working through an existing foreign trading enterprise, Polservice, Posteor can earn valuable hard currency marketing know-how and licences abroad as well as protecting Polish patent rights. Through its exhibition at the Fair, Posteor hopes not only to increase its foreign outlets, but also to sell its technology and expertise at an earlier stage of development. "We can exhibit ideas, pilot technologies and know-how," explained one representative, "even if we haven't ironed out all the snags of full-scale production."

The small selection of projects on display is indeed wide-ranging: it includes a method for producing phosphates as a by-

product of sulphuric acid manufacture, and practical expertise in geodesy and water surveying, as well as an analogue system for measuring the field distribution near high voltage power lines — Poland will have its first 350 MW lines next year, as part of the Comecon supergrid. A method of cutting the petrol consumption of the average automobile by 15% underlines the importance of energy saving in the Posteor exhibits: other examples range from a cold-hardening process for worm-drive castings down to a method of freeze-drying whole potatoes. Indeed, energy conservation is a major theme of the entire Polish display, from the generating sets exhibited by Elektrim to the coal-mining pavilion with its placards extolling the leading role of the coal industry.

Following a winter when exceptional weather conditions led to a total halt in production, Poland is now rethinking one aspect of her energy policy, the proposed compensation deal with Austria. Under this agreement, Austria would build hydroelectric generating stations on the Bug, and in return would take two thirds of the current produced for the next 25 years. This scheme — like the proposal for a trans-Czechoslovakia pipeline to carry coal dust to Austria — is dear to the heart of Austrian trade minister Joesef Staribucker, and such deals are normally popular with the Polish planners because they save hard currency by paying in kind rather than cash. But it is now most unlikely to go through, for, as the Polish vice-minister of trade, Edwin Wisniewski, told journalists at the Fair: "Coal and energy are now far too precious for compensation deals. We shall always be willing to sell them, so long as we have them to sell — but it must be strictly for cash." **Vera Rich**

## news in brief

**UK government scientists to strike:** The Institution of Professional Civil Servants is continuing its industrial action through a series of selective strikes. Now scheduled for action are the government laboratories of the Agricultural Research Council and the Science Research Council. Also included will be the Central Veterinary laboratory at Weybridge, the Royal Aircraft Establishment in Farnborough and forensic scientists in the Home Office. The union is demanding pay rises linked to administrative grades for this year and an appropriate linking to outside salary structures for next year. (See leader comment.)

**US-Europe to collaborate on testing cloning risks:** The first results of a European attempt to assess some of the proposed hazards of the techniques of recombinant DNA (see p 811) help to define the way in which the next step in risk assessment should be carried out. It is a step, however, which cannot be carried out in Europe — because of the lack of animal facilities that meet the level of safety that is now required to avoid the conjectured risks that the experiment would attempt to assess. To escape from that predicament the European team will go to the US to collaborate with Dr W Rowe and his colleagues who have been carrying out a parallel study using the animal facilities at Fort Detrick. Both groups are testing whether the cloned genome of a tumour virus retains the ability to be infectious and to cause tumours. The Americans have already carried out some animal tests and will now be repeating them with the virus cloned in Europe.

**SIPRI criticises increased NATO military spending:** The Stockholm International Peace Research Institute, in its annual report, is sharply critical of NATO countries decision to increase their military spending by 3% a year. The SIPRI report states that the increased expenditure has been based on "dubious" propositions about USSR spending produced by US intelligence agencies. US intelligence has estimated that Soviet spending exceeds US spending, that it is taking an increased share of Soviet GNP and that it has been rising by 3% a year in real terms for a long time. According to SIPRI these estimates are constructed by converting labour intensive Soviet manufacturing into US capital intensive costs thus leading to an overestimate of real spending. "Valuing the military output of a much more labour intensive country such as the USSR at US prices distorts the actual situation" the report says. SIPRI also criticises the USSR policy of concealing defence spending, which it says contributes to the construction of exaggerated estimates of its spending.

The SIPRI report also warns that improvements in missile accuracy are leading to new nuclear war strategies. The old 1950s policy of mutual deterrence is giving way to a "counter-force" strategy. A new generation of missiles will be able to strike within tens of metres of hardened missile sites thus giving governments the "misplaced confidence that they can actually fight and win nuclear wars rather than simply deter them". (World Armament and Disarmament. SIPRI Yearbook 1979. Taylor and Francis Ltd, London.)

**Sussex students win reinstatement:** Sussex students Richard Flint and Shaun Fensom (21 June) were reinstated last Monday by a specially convened disciplinary committee. They had been "excluded" from campus for participating in a student union mandated examination disruption. The students were warned they would be excluded if they participated in further examination disruptions. Students have called off plans to disrupt conferences at the university this summer and the outstanding issues will be joined again in the Autumn. First year science students will decide at a mass meeting whether to continue the boycott of the preliminary science examination and the student rent strikers await the outcome of a university Senate meeting on student debt. The disciplinary committee decision followed another week of militant student action.

**US prepares for military intervention in oil crisis:** The US government announced Friday that it has established a "unilateral corps" of 110,000 men from Army, Navy, Marine and Tactical Air Force units. The corps will operate outside of NATO control and are ready for combat "in all theatres of operations where US interests are threatened". The special force will be dispersed among conventional military bases but will be mobilisable for rapid intervention at "hot points". Department of Defense head, Harold Brown said that the DOD currently is improving its sea and air transport facilities "so that we can get special units to various places distant from the US and Europe rapidly". Speaking at a press conference attended by Chief of Staff B. W. Rogers, Presidential adviser Z. Brzezinski, and Secretary of State C. Vance, Brown acknowledged that US dependence on oil imports was a serious potential "security" problem. The US gets 25% of its oil from the middle east. Brown emphasised that the US was seeking political solutions in the middle east and was consulting with moderate Arab states "which are understandably concerned about the possibility of outside intervention".

**Strict new rules on the transport of nuclear waste:** The US Nuclear Regulatory Commission recently published a strict set of rules covering the conditions under which spent nuclear fuel can be transported by road. These include the requirement that the NRC inspect and approve the route that each shipment is expected to take, that law enforcement agencies be informed in advance, and that each shipment be accompanied by guards knowledgeable about both the route, the cargo and emergency procedures.

The new rules have a dual purpose: to protect the public against possible accidents (all routes must, wherever possible, avoid major cities and urban areas), and to guard against the dangers of hijacking. To cover the latter, for example, the rules require that all vehicles be equipped with features that "permit immobilisation"; among proposals previously discussed for achieving this are dashboard buttons that would simultaneously blow out all the truck tires, explode the engine, and set off a wailing siren.

Antinuclear groups have already attacked the adequacy of the new regulations, which although they go into effect immediately, will be open for public comment for 45 days. They have challenged the first route that the NRC is now studying for approval between Norfolk, Virginia, and the Department of Energy's reprocessing and storage plant at Savannah River in South Carolina. This route would be used to transport spent fuels being brought in from abroad; anti-nuclear groups such as the Potomac Alliance argue that incoming ships could dock closer to Savannah River, and are therefore questioning the proposed route through Norfolk.

**Bellerive Group attacks pro-nuclear lobby:** The Bellerive Group, an international body of experts which includes Victor Weisskopf, a former director of CERN, has issued a stinging critique of conventional arguments in favour of nuclear power. Proponents of the orthodox pro-nuclear case have refused to answer the severe criticisms of their basic assumptions, the report says. These include assumptions about future electricity demand, patterns of energy use, and the possibility of expensive energy savings measures. Other criticisms are the inapplicability of nuclear generated electricity for transportation needs and the wastefulness of using nuclear generated electricity for space heating. The report also raises the dangers of nuclear proliferation and the possible dangers to civil liberties. The report warns that disaffection with society because of the nuclear issue "is greater than the nuclear industry and some governments that support it now realise. No free society can be governed without both trust and consent. Once trust evaporates government can be carried on only by increasing coercion".

# Urban deprivation in the heart of the Amazon

by David Bousfield

THE city of Manaus lies high on the Amazon, at the junction of the Rio Negro and the Rio Solimões. During the last century it was the centre of the rubber industry in Brazil, and the magnificent Opera House, decorated largely with materials imported from Europe, still testifies to its former wealth and importance. Since those times, however, the area has been in decline and today the State Governor complains that the development grant intended for the whole of the Amazonas region is less than that given to the Tourist Department at São Paulo in the south. Recently Manaus was made a free port in an attempt to stimulate the local economy, but despite its attraction to Brazilian tourists, who travel thousands of miles to buy cheap cameras and hi-fi, this isolated town in the heart of the Amazonian forest retains all the problems of urban underdevelopment found elsewhere in the north and north-east of Brazil.

Manaus is fortunate, however, in having on its outskirts the principal administration and research complex of the National Institute for Amazonian Studies (INPA). This department has 107 scientific staff, while the other main department, at the Museu Goeldi in Belém has 51 scientists; in addition there are a number of research stations scattered over the Amazonian area. Under the Directorship of Dr Warwick Kerr, a geneticist from São Paulo, INPA's research projects have been directed at local problems. "INPA is always canalising effort towards the benefit of the people of Amazonia", he comments. Consequently research carried out by INPA includes work on fish farming, ecologically appropriate approaches to agriculture, malnutrition, and the impact of disease on settlement along the Transamazonian highway.

The rapid development of the fragile forest environment has created many problems for urban and rural colonists alike. For example, the 3,000 km Transamazonian highway, completed in 1975, was originally intended to allow families from the drought plagued north-east to colonize the forests. Yet the agricultural advice given to these would-be farmers by David Bousfield, of the University of Sussex, held a Nature Travelling Fellowship

INCRA, the Government colonisation agency, was not based on detailed research or planning. Indeed the route taken by the highway had already been decided, and some of the first colonists settled before the main soil survey work was carried out. Upland rice was envisaged as the principal cash and subsistence crop, but INPA geographer Nigel Smith has found that a better choice would be a more diversified crop base including manioc. Diversity reduces pest damage and means that income is not dependent on the success of a single crop. Indeed Dr Smith finds that the optimal farming strategies emerging from his work bear a striking resemblance to the methods of the Indians who used to live on the land now occupied by colonist settlements.

## Mixing European and Indian crops

Since the colonists have little knowledge of which crops they should plant, additional work by INPA includes the selection of European varieties of fruit and vegetables such as carrots, cauliflowers and citrus, which are suitable for local soil conditions and climate. Attempts are also being made to reintroduce local fruit such as assaí and bacabá into the Amazonian diet, and the Indian heritage has also been useful here since many Indian tribes actively cultivated the plants which produced the best fruit. The sapota, for instance, normally produces fruit weighing 80-100g, but the Tipuna Indians have managed to increase this to hundreds of grammes, and have trees which can yield up to 11 tonnes of fruit in one harvest.

Perhaps the most interesting example of INPA's concern for the Amazonian people, however, can be found in the nearby 'favela' in the Coroado district of Manaus. This slum town is built on private land invaded by the poor some six years ago. There are now over 25,000 people living in shacks made from wood, corrugated iron and even cardboard without any form of sanitation or a proper water supply. In 1977 INPA bought one of these houses and set up a school, thus providing a valuable base for research, and for establishing some interaction between the various departments of INPA and the people of the favela. The school's name, 'Escolinha da Abelinha', which can be translated as the 'Little School of the Busy

Bee', reflects the determination and sense of humour of Dr Kerr and its first teacher and director, INPA educationalist Margie Charlwood.

By concentrating on pre-school education (children aged between 4 and 6), INPA has made a considerable contribution to the nutritional and educational development of the children of Coroado. Some 48% of the children entering State schools at 7 have to repeat their first year courses, and as a consequence many become frustrated and never go back. Pre-school education helps to avoid this early trauma, and it is a strategy now advocated by UNICEF. Even the simple measure of providing regular meals improves exam success: 73% of children in the pre-school age range suffer from malnutrition and many show signs of physical and mental retardation. By isolating the main dietary deficiencies and by trying to counteract them at the school, Charlwood and INPA nutritionist Roger Shrimpton hope to improve infant feeding habits and nutritional status.

Traditionally much of the food for Manaus has been imported. In 1975, for example, the region only produced 25% of its requirement of rice and meat, only 12% of its milk, and it imported nearly all its fruit and vegetables. The resultant expense creates some rather unexpected dietary deficiencies. Despite being surrounded by a forest containing many edible species of plant, the inhabitants of the city consume per capita only one-half the amount of fruit and one-third of the green vegetables eaten in São Paulo, and so deficiencies of vitamin A, thiamin, riboflavin and iron are common.

Bad diet preferences are also partly to blame for nutritional problems. In the days of the rubber barons the best pâté and champagne were readily available in Manaus, and today the freedom from import tariffs continues to encourage specialist tastes. The current school meals programme run in State schools and backed by the FAO includes Norwegian cod, Dutch cheese and crystallised fruit to supplement children's diets. INPA workers argue that this programme is merely creating markets for richer countries' unwanted products rather than teaching children how to feed themselves. Consequently attention is now being fo-

*Incongruous Manaus: amid the poverty, the Opera House is a reminder of former glories*

cused on the possibilities of using local varieties of fruit and vegetables.

Various diets are being introduced to the children of the Bee School and their acceptability and nutritional impact assessed. The mothers are actively associated with the running of the school and contribute to the preparation of these meals, ensuring that the educational process is not restricted to the children and the bond between the school and its community is strengthened. At the same time simple rules of basic hygiene and nutrition are being incorporated in the curriculum. An elementary reading and spelling exercise book, or 'cartilha', written by a team including Dr Kerr contains advice on which foods contain calcium and how to take care of teeth.

It is too soon to assess the project's eventual success, although the number of children attending the school has risen from 30 to 220 during its first two years, and after six weeks of the supplementary school meals their average weight increased by two kilogrammes. Once a cheap and nutritious diet has been developed, INPA would like to see the scheme extended to other 'favelas' as part of a scheme of development for the whole region.

Unfortunately the relationship between science and the solution of social problems elsewhere in Brazil is much less apparent than in Manaus. Many scientists I spoke to in the south felt that the social problems of the country (one-third of Brazil's children, some 16 million, live in slum communities) could be solved simply by political reform and government aid. But it was also clear that in the sophisticated intellectual climates of cities such as Brasilia and Rio de Janeiro a preoccupation with Western science is leaving little time for considering how the problems facing the urban and rural poor might be approached. Now Kerr and his co-workers have lead the way, will others follow? □

## Asian scientists agree on development issues

**Yonguth Yuthavong** of the Department of Biochemistry, Mahidol University, Bangkok reports on a lively meeting in Kuala Lumpur

SCIENTISTS from 21 South and South-East Asian countries met last month in Kuala Lumpur, Malaysia, and agreed on six basic principles to improve science and technology in their countries.

The meeting, organised by the Committee on Science and Technology in Developing Countries (COSTED, a body set up by the International Council of Scientific Unions), concluded that:

- Since the general level of indigenous scientific and technological capability is very low, and varies greatly among developing countries, more emphasis should be placed on regional sharing of scientific competence.

- There should be increased representation of scientists and technologists from developing countries in international bodies dealing with science, technology and development. Possible measures include travelling fellowships and the establishment of international institutions in the developing world.

- Effective and socially relevant science and technical education is one of the most important factors contributing to development. International support is needed for preparation of suitable educational material and for training of personnel, but care should be taken to promote self reliance in the education programmes of the developing countries.

- Suitable scientific and technological information systems should be established, oriented towards important issues in development.

- To make UNCSTD a success, a follow-up mechanism to implement its decisions must be speedily established.

- It was of particular importance, the meeting decided, to define the goals of development as clearly as possible. The meeting emphasised the provision of basic needs for people — rather than high per capita GNP. The Association for the Application of Science to Human Affairs (ASHA), composed of a group of scientists in India and supported by COSTED, has proposed the ASHA Development Index (ADI) based on parameters of health, literacy and employment ( $ADI = \text{per capita GNP growth rate} \times \text{employment} \times \text{literacy} \times \text{life expectancy fraction} [70 \text{ yr} = 1.00] / \text{birth rate} \times \text{infant mortality}$ ). The ADI was found to vary from 43 for poor countries to over 10,000 for rich countries. The goal advocated by ASHA is an index of over 2000 by the year 2001. While there is at present a general correlation between GNP and ADI, the meeting agreed that strategies for future development should aim to raise ADI, rather than GNP simply through rapid industrialisation with depletion of resources and urbanisation.

The lack of an effective scientific and

technological infrastructure in the developing world is reflected by various indicators: number of scientists and technologists, number of institutions, amount and quality of publications and other output. A survey of papers published in international journals showed that a very small fraction originated from developing countries. It is striking that India contributes about 5,000 papers per year (in journals covered by *Current Contents*), half of the total output from all developing countries and far more than South Africa or Brazil. The amount of research output alone therefore does not bear a simple relationship with the state of development of a country. It was generally agreed that to promote development in a poor country most effectively, not only must the research be of high quality but also the deal primarily with unique resources or pressing problems of the country. Good examples are rubber research in Malaysia and diarrhoeal diseases research in Bangladesh. This demands keen awareness of the researchers on various aspects of priority research areas — an awareness which is lacking, given the present communication gap between the scientists, the industrialists and the general population in the developing world. A remedial mechanism was proposed in which the scientists, the industrialists and the citizens could mutually interact in forums organised by the professional societies and government or private agencies. In addition, novel structures of reward and recognition should be devised to encourage research interests in development-related areas.

The meeting also emphasized the value of science as creative activity for the enquiring mind. The scientist, however, tends to become alienated from his society if his work has little relevance to its problems. A conscious effort should therefore be made by the scientific community to bring social relevance into their work, while preserving the role of making enquiry for more basic knowledge at the same time. A proper balance between basic and applied science would depend on the level of development, resources and constraints of each developing country.

It was felt that there was a need for novel scientific and technological information services orientated towards development problems of the Third World. Suitable services should be available not only for scientists and technologists, but also for administrators, field or extension workers and the general population, mostly illiterate farmers and small scale village industrialists. The problems foreseen are enormous, and

proposed solutions ranged from creation of a new information system on science and technology for development, to provision of information materials to the developing countries at a moderate cost, and promotion of public understanding of science and technology through mass media. International information agencies, scientific unions and private publishers can play substantial roles in these schemes. It was argued, for example, that sale of books and journals to the developing countries is only a minor fraction of the total sale, and the publishers should consider reducing the prices to a level which these countries can afford. Schemes for book donation such as operated by UNESCO should also be made more effective.

Nowhere is the need for public understanding of science and technology more acutely felt in the developing world than in the fields of health and agriculture. Many tropical diseases are largely preventable: hookworms are prevented by wearing shoes, cholera by having clean water supply, xerophthalmia by eating food containing vitamin A, etc. The yields of major food crops can be

increased several fold through proper fertilizer supplies, pest management and irrigation. Apart from the fact that money and supplies are simply not available, the necessary information is also not accessible to the majority of the rural population. Technology transfer for village industries also present similar problems. The development of extension services and non-formal education deserve high priority.

The strengthening of the scientific and technological capacity of the developing world will be both expensive and time-consuming. Some delegates even expressed despair that this goal will ever be significantly achieved in the majority of developing countries. An alternative goal was proposed whereby a group of countries within the same region would share their resources and pool external aid in a limited number of large and effective institutions. While this arrangement could possibly be of benefit for certain projects which need a considerable amount of scientific infrastructure, its main drawback is the continuing dependence of the smaller and less developed countries, their big brothers merely being in the same

region rather than somewhere to the North. Whatever the strategy, it was clear that much more co-operation from the developed countries should be forthcoming. This will have to include provision of scientific equipment and maintenance facilities, information, help in scientific and technical education, exchange of scientists and technologists. The developing countries themselves will have to try harder to support their scientific and technological activities, including education.

Developing countries often have an asset in abundance of natural resources, solar energy supplies and a climate suited for rapid bioconversions. The meeting agreed that these local advantages should be utilized, which implies that the problems for science and technology will often be very different from those in developed countries. It was proposed that a consortium of experts from the developing countries be formed to deal with training and development of technology for optimum utilization of natural resources. It is hoped that international agencies including COSTED will take up this matter further. □

## Hunting Mongolian dinosaurs

COMECON, in the thirty years of its existence, has provided the framework for numerous scientific cooperation projects. One of the most interesting and most unusual was the Polish-Mongolian series of palaeontological expeditions of 1963-1971, organised by Dr. Zofia Kielan-Jaworowska of the Polish Academy's Institute of Palaeozoology. (For the latest results, see p 792.)

These expeditions not only produced a wealth of scientific material on dinosaurs, dinosaur eggs and mesozoic mammals, which is gradually being published in *Palaeontologia Polonica* (the final report is expected to extend to some 16-20 thick volumes; No. 8 is now about to appear); they also resulted in an excellent "popular" book on palaeontology — Dr. Kielan-Jaworowska's *Hunting for Dinosaurs*. Most important, perhaps, as I learned when I spoke with Dr. Kielan-Jaworowska in Warsaw, they provide a fascinating commentary on how formal "scientific cooperation" can work.

Not that the Gobi expeditions were entirely typical! Cooperation agreements within Comecon tend to take place between the Soviet Union and one or more of the smaller member-countries — a major project without Soviet participation is somewhat rare. In fact, Dr. Kielan-Jaworowska explained, at the beginning there was some talk of Soviet participation, but the Soviet Palaeontological Institute was "too busy."

The idea for such an expedition arose in 1961, when the representatives of the Comecon Academies of Science met in

Warsaw. During this meeting, a cooperation was signed between the Polish and Mongolian Academies, and Dr. Kielan-Jaworowska put forward a proposal for joint palaeontological expeditions. "This was my private dream," she explained, "and also the dream of many workers in this institute. Mongolia is an unusual country, especially for vertebrate palaeontology. The odd thing is that we were invertebrate palaeontologists at the time!"

In due course, Dr. Kielan-Jaworowska was appointed to lead the expeditions. One of the main practical problems was, of course, that Poland is among the most scientifically advanced Comecon countries, while Mongolia is relatively backward. For the project to be genuinely bilateral, some preliminary training was necessary. "We had to help the Mongolian Academy," she said. "We had to teach their scientists. They came during their training to our institute and we published some joint papers. At that time there were about ten Mongolian palaeontologists working in Ulan-Bator. Two of these — Demberelyin Dashzeveg (a specialist on mammals) and Rinchen Barsbold (dinosaurs) — were very gifted."

The field-work of the expeditions proved successful beyond all hopes. Major finds included dinosaur eggs, fossil tortoises, many new genera of dinosaurs, and, for the first time, well-preserved skulls of multituberculates, which threw new light on the mesozoic "dark ages" of mammalian history. Subsequent study of the multituberculate finds showed that these non-placental mammals were closely related to

On the trail: Dr Kielan-Jaworowska (right) and colleague

the monotremes as far as brain structure was concerned, thereby raising the further question of whether they were viviparous or oviparous.

Poland has an excellent network of museums, Mongolia has simply the municipal museum in Ulan Bator. One might be tempted, therefore, to imagine that the bulk of the material will remain in Poland. "Not at all," said Dr. Kielan-Jaworowska. "The agreement is that after we have studied the material, part of it will be sent back to Ulan Bator."

"There will be a true pay-off for both sides," she added. "We have got some most interesting material, which throws great light on some of the most important questions of evolution. And the Mongolians will get good material and the basis for a good museum."

## Guest species in minerals and other crystals

from J.M. Thomas

So widespread is the occurrence of isomorphous and other forms of substitution that their nature and consequences are the concern of chemists, solid-state physicists and mineralogists alike. When a guest species is present either in small quantities or in rather large but non-stoichiometric amounts, the determination of its precise crystallographic location is seldom a simple affair. A good deal of the evidence pointing to the phenomenon of site substitution came originally, and indirectly, from a combination of simple chemical principles and accurate wet chemical analyses. It was soon established that, among the numerous kinds of silicates that constitute the rock-forming minerals, there is a tendency for  $\text{Al}^{3+}$  ions to occupy tetrahedral sites normally tenanted by Si and for  $\text{Mg}^{2+}$  to replace  $\text{Fe}^{2+}$  or  $\text{Al}^{3+}$  in octahedral sites. Similarly  $\text{Li}^+$  replaces  $\text{Mg}^{2+}$  in sites of sixfold coordination. The negative charge borne both by the framework zeolites, that nowadays play such a crucial role in the catalytic cracking and synthesis of hydrocarbons, and by the sheet silicates, which are responsible for the cation-exchange capacity of clays, is a direct consequence of this kind of substitution. Site-substitution and site-selection are also implicated in trace-metal segregation and enrichment; and thermodynamic arguments that apply to geothermometry and geobarometry (Navrotsky *Prog. solid state Chem.* **11**, 203; 1976) rely, in turn, on experimental methods of ascertaining site identity and occupancy.

X-ray crystallography, from its inception, has, in favourable circumstances, offered a more or less direct means of assessing the extent of site substitution. But in view of the factors that govern the scattering of X-rays, this approach is not well-suited to discriminate ions of elements possessing closely similar atomic numbers. Thus, whereas the pairs  $\text{Ca}^{2+}$  and  $\text{Mg}^{2+}$ ,  $\text{Sr}^{2+}$  and  $\text{Ba}^{2+}$ , or  $\text{K}^+$  and  $\text{Na}^+$  are readily distinguishable both on grounds of scattering power and ionic radius, it often proves difficult to identify  $\text{Si}^{4+}$  sites that are occupied by guest  $\text{Al}^{3+}$ . X-ray methods encounter a similar difficulty when  $\text{Fe}^{2+}$  is replaced by  $\text{Mn}^{2+}$  or vice versa, especially if the extent of substitution is small or if the guest ions are randomly distributed within the host matrix.

In seeking alternative approaches, much progress has been achieved by spectroscopic methods, which involve monitoring the frequency, intensity and band profiles of absorptions in the infra-red and visible regions of the spectrum. Mössbauer spectroscopy, though of restricted applicability, has contributed much to knowledge of site population and preference, especially in ferrous and ferric ions in amphiboles, pyroxenes, garnets and biotites (Bancroft, Williams and Burns, *Am. Mineral.* **56**, 1617; 1971). (Conversion electron Mössbauer spectroscopy, which is even more restrictive in its applicability, has also been particularly powerful in ascertaining site characteristics in certain sub-surface phases — see Tricker, Winterbottom and Freeman *J. Chem. Soc., Dalton Trans.* 1289; 1976.) Recently, however, electron spectroscopy has burgeoned, and although its direct application has contributed little to the elucidation of site occupancy, a rather novel development (termed XPD for reasons given below) has now made possible new insights into the crystallography of various naturally occurring and chemically modified minerals. The technique is simple, straightforward and widely applicable, provided reasonably sized single-crystal specimens are available.

X-ray-induced photoelectron spectroscopy (XPS) entails the measurement of the kinetic energy of electrons liberated when a material is irradiated with monochromatic X-rays. From the known energy of the latter the binding energy of the core electron (for example, K 2s, Al 2p, Fe 3p) may be evaluated. The precise value of the core-electron binding energy is a function of the environment experienced by the atom from which the electron is emitted. But the magnitude of the 'chemical shift' in binding energy exhibited by a given ion in two or more crystallographically distinguishable sites is disappointingly small (Adams, Thomas and Bancroft *Earth Planet Sci. Lett.* **16**, 429; 1972) and inadequate to serve as a trustworthy basis for site identification. Fortunately a more subtle use of XPS can be envisaged. This entails monitoring the 'diffraction' of the X-ray-induced photoelectrons (XPD) as the take-off angle of the emitted electrons is varied. Although the existence of this diffraction has been

known for some years (Siegbahn, Gelius, Siegbahn and Olson *Phys. Lett.* **A32**, 221; 1970; Fadley and Bergstrom in *Electron Spectroscopy* (ed. Shirley) 233; North Holland, Amsterdam, 1971) its potential value in structural elucidation of the near-surface regions of solids does not seem to have been recognised previously, in spite of the early observation by Fadley and Bergstrom (1971) that the angular dependence of the XPS signal from silver dissolved in single-crystal gold was essentially identical with that of the gold. The structural elucidation of complex solids by XPD has been described recently by Adams, Evans and Thomas (*J. Am. chem. Soc.* **100**, 3260; 1978).

Suppose the angular variation of the intensity of the Si 2s photoemitted electrons of phlogopite mica is monitored. The intensity fluctuates because of the (multiple) diffraction that the electrons suffer between the point of generation inside the crystal and their escape into the vacuum. If, as was originally suggested by Mauguin (*C.r. hebdom. Seanc. Acad. Sci.* **156**, 1246; 1928) and Pauling (*Proc. natn. Acad. Sci. U.S.A.* **16**, 123; 1930),  $\text{Al}^{3+}$  ions occupy some of the tetrahedral sites normally taken up by  $\text{Si}^{4+}$ , then the angular variation of Al 2p and Si 2p photoelectrons (or of Auger electrons emitted from these atoms) should be identical, a situation which would certainly not obtain if  $\text{Al}^{3+}$  were preferentially or additionally resident in octahedral sites. By taking intensity ratios (for example, Si 2p/Al 2p or F 1s/O 1s), rather than absolute values for single core levels, sources of experimental and related uncertainty (caused, for example, by eccentricity of the specimen mount), are eliminated, and comparison of site substitution in one specimen with near- or exactly-equivalent substitution in another is rendered possible. (Moreover, the essential invariance of K 2p/2s and Si 2p/2s ratios with angle demonstrates that differences in electron wavelength and radius of ionised shell are of secondary importance.) Using this simple qualitative approach, Evans and collaborators (*Phil. Trans. R. Soc.* in the press) have re-examined critically the hitherto accepted site assignment of a range of micas. In addition to presenting direct proof that  $\text{Al}^{3+}$  ions are indeed accommodated only in the ( $\text{Si}^{4+}$ ) tetrahedral site in phlogopite, they also demonstrated that the  $\text{Mg}^{2+}$  ions

in vermiculite and the  $\text{Al}^{3+}$  ions in lepidolite are in identical crystallographic environments, both being situated at octahedral sites. Moreover, XPD shows that ions (such as  $\text{Na}^+$ ) present in muscovite in quantities too small to be detected by conventional X-ray methods, occupy sites that are similar, but not exactly equivalent, to those occupied by the interlamellar  $\text{K}^+$  ions which they replace.

By its nature the technique is more reliable the smaller the extent of substitution, and it does not require the guest species to be ordered (contrast X-ray diffraction). And although it is biased in favour of the sub-surface regions (about 100 Å) of the crystal — because of the magnitude of the electron escape depth — it possesses further advantages in that, combined with measured XPS intensities and known photoelectric cross-sections, it affords insights into the degree of hydration of exchangeable cations. Thus it has been established (Evans, Adams and Thomas *Phil. Trans. R. Soc.* in the press) that, whereas interlamellar  $\text{Ca}^{2+}$  or  $\text{Pb}^{2+}$  ions in weathered or solution treated vermiculite are shrouded with a hydration shell, interlamellar  $\text{K}^+$  ions, on the other hand, are bare. In similar vein, Evans (in preparation) has recently shown that substitutional titanium ions in the mineral biotite occupy both tetrahedral and octahedral sites (the approximate percentage population being 30 and 70 respectively). Furthermore, he reported at the European Conference on Surface Science (ECOSS2) in Cambridge, March 1979, that, by recording intensity variation as a function of azimuthal angle (at a fixed polar angle) information about site symmetry (of the photoemitting atom) may be gleaned. In this respect, XPD is formally akin to the more strictly surface tools that utilise angular variation of core-level electrons liberated (by X-rays or synchrotron radiation) from adsorbed phases. These tools have been applied with conspicuous success by Kono, Fadley, Hall and Hussain *Phys. Rev. Lett.* **41**, 117; 1978) who succeeded in extracting information on both the symmetry and bond lengths associated with oxygen chemisorption on copper, and by Woodruff, Norman, Holland, Smith, Farrall and Traum (*Phys. Rev. Lett.* **41**, 1130; 1978) who arrived at quantitative surface structural information relating to the adsorption of Te and Na on Ni(100) faces.

It seems clear that, provided experimental methods can be evolved to cope with smaller single-crystal specimens, a wide range of structural and thermodynamic problems in geochemistry, as well as in materials and engineering science, should be clarified by the application of XPD. □

J.M. Thomas is Professor and Head of the Department of Physical Chemistry at the University of Cambridge.

## Proline and folding proteins

from Robert Freedman

A FOUR-YEAR-OLD hypothesis that the imino acid proline has a special role in the folding up of proteins has been confirmed, refined and extended by several, almost simultaneous publications from laboratories in Britain, the United States, Switzerland and the Federal Republic of Germany. One of the papers gives a detailed picture of how the complete three-chain protein collagen, the main protein in tendons and cartilage, folds itself up. Proline is unusual among the components of proteins in that it is an imino acid rather than an amino acid. This gives it unique and long-recognised properties of restricting the folded structures a protein can take. But it has become apparent recently that prolines may also control the rate at which proteins can fold up from an unfolded state.

Thirty years ago, Linus Pauling showed that in most peptide bonds, the side chain groups of the amino acids ( $\text{R}_1$  and  $\text{R}_2$  in Fig. 1) are held as far apart as possible in a *trans* configuration for the peptide bond. This is much preferable to the more crowded *cis* arrangement. But for bonds involving the NH group of proline both *trans* and *cis* arrangements are possible; the *trans* configuration is still slightly preferable and is found more often in folded proteins, but in an unfolded protein the *cis* form of the bond could easily occur. If that were the case then the process of getting proline peptide bonds into the right configuration would be important in the folding up of proteins.

In 1975, Brandts, Halvorson and Brennan (*Biochemistry* **14**, 4953) collected data on the folding of proteins and pointed out two important facts. For many proteins the folding process occurs in two phases and the rate of the slow phase is very similar to the rate at which proline peptide bonds isomerise — interconvert between *cis* and *trans*. To explain this, they proposed that only the unfolded molecules with all their proline-containing peptide bonds in the correct configuration could fold up. So the fast phase corresponded to the folding of the molecules which were all correct at the start of folding, while the slow phase corresponded to the slow isomerisation of the remaining molecules.

Gradually the data have accumulated to support this interpretation. Over the years Baldwin and colleagues at Stanford have analysed the slow and fast phases of refolding of ribonuclease in great detail. Now, he and Schmid have shown that the slow phase is the result of slow isomerisation of peptide bonds involving proline, but their quantitative data do not exactly agree with the model originally put forward (*Proc. natn. Acad. Sci. U.S.A.* **75**, 4764; 1978). This proposed that all the peptide bonds in the unfolded protein would have to isomerise to the correct configuration before folding could begin. The data of the Stanford group suggest that not all the bonds need to be correct; there may be some 'permissive' proline residues which can be fitted in, either in the *cis* or the *trans* configuration.

Similar modifications of the theory have been suggested by Creighton, who has considered the problems facing a large protein containing a lot of proline residues (*J. molec. Biol.* **125**, 401; 1978). Whereas the slow phase of refolding for the small proteins mentioned above is of the order of a few seconds, Creighton shows that for a protein containing 20 proline residues it would be about 10 min, and would stretch into hours for a protein with 30 proline residues. These figures are so unreasonably large that modifications to the model have to be considered. There are two related possibilities. The protein could be divided into domains each of which can fold independently; the folding of each domain would be as fast as that for a small protein and the whole molecule would soon be fully folded. Alternatively, without a clear division into domains, a protein could nevertheless fold itself up bit by bit, the region around a 'correct' proline folding to its final conformation without having to wait for all the prolines in the molecule to be in the right configuration.

The former of these proposals, domain organisation, is probably what happens in most globular proteins. But for collagen, a fibrous structural protein, there is now direct evidence for the second — 'bit by bit' — hypothesis, from the work of Bächinger, Bruckner, Timpl and Engel (*Europ. J. Biochem.* **90**, 595, 605; 1978). This collaborative group based at Basle and Martinsried has isolated a fragment of procollagen which on a small scale resembles the whole collagen molecule. This fragment (peptide Col 1→3 of bovine type III procollagen) consists of three poly-

Fig. 1

Fig. 2

peptide chains, the central regions of which are twisted round each other in the 'triple-helical' structure characteristic of collagen. At the end of the triple-helical region, the chains are fixed to each other by a kind of knot formed by disulphide bonds between the chains (Fig. 2). Bächinger *et al.* have unfolded this fragment and studied its folding as a model of the folding of collagen itself.

The interesting point here is that the Col 1→3 fragment, like collagen itself, is very rich in proline residues and hydroxyproline residues. The whole fragment has 27 such residues in each of its three chains so that they make up 20 % of the protein; in the triple-helical region they comprise one-third of all the residues. But Col 1→3 folds into its complex triple-helical structure in not much more than a minute. Is this speed consistent with the hypothesis that proline peptide configuration is crucial to folding?

The group from Martinsried and Basle showed that peptide bond isomerisation was important by a neat experiment. When they refolded Col 1→3 from the unfolded state it folded in two phases. But the proportion which refolded fast was greatest when they used material which had only just been unfolded. In other words, if you unfold the protein and immediately try to refold it, most of it can refold rapidly;

but if you wait before refolding it, the proportion which refolds rapidly, diminishes progressively. This suggests that immediately after unfolding all the bonds are in the correct configuration for folding, but that they gradually isomerise and incorrect configurations accumulate. All the thermodynamic parameters of the folding and unfolding also showed that the isomerisation of proline peptide bonds was the rate-determining step.

So how are all the proline peptide bonds isomerised so rapidly? The answer is that the process can occur bit by bit. The disulphide knot is a nucleus from which folding can begin. Then the three chains can begin to twist themselves up correctly until they come to a proline in the wrong configuration. Once that has isomerised they can proceed as far as the next wrong one and hence the folded structure is rapidly propagated. Because the protein here is essentially a linear cable, rather than a tangled mass like globular protein, folding can proceed in this stepwise manner, rather than being an all-or-none process which depends on all the proline residues being in the correct configuration at the start. □

Robert Freedman teaches biochemistry at the University of Kent, Canterbury, UK.

## West African membrane controversy

from Peter J. Smith

SOME years ago Turcotte and Oxburgh (*Nature* 244, 337; 1973) introduced the fascinating concept of 'membrane tectonics' to explain certain aspects of the internal tectonic behaviour of the Earth's lithospheric plates. The idea is simply that plates, being thin shells in relation to the Earth's radius, should act as membranes, the theory of which has long been familiar to civil engineers and the like. Specifically, as the Earth is an oblate spheroid rather than a perfect sphere, any plate moving from one latitude to another will experience a change in curvature and all that results from it. Generally a plate travelling away from the equator will find its curvature decreasing and its periphery under tension, whereas a plate approaching the equator will increase its curvature and experience peripheral compression. A moving plate will thus be subjected to deformation, stresses and consequent secondary phenomena such as fracturing.

As possible examples of membrane tectonics in action Turcotte and Oxburgh suggested Hawaii and East Africa; but later Freeth (*Earth Planet. Sci. Lett.* 38, 298; 1978) was to put forward what he held to be "an even better example", namely, West Africa and the Gulf of Guinea. It is difficult of course to apply simple membrane theory to a plate containing an inhomogeneous continent with an irregular outline, not least one that for more than 100 M yr has been growing (by accretion at the mid-Atlantic ridge) and parting from a once-joined continent (South America). Nevertheless, Freeth managed to convince himself that in the West African rift zone (chiefly the Benue, Yola and Gongola rifts), compression and tension occurred in the way one would expect for a region first approaching the equator and then receding from it in the northerly direction.

Thus as the West African rift system

moved towards the equator from the south 90–40 M yr ago it underwent compression, resulting in folding, the eruption of andesites (implying subduction) and the development of mylonite zones. But while the region was in the vicinity of the equator about 40 M yr ago there was little or no tectonic activity. Then during the past 30 M yr or so, as the area has moved away from the equator, there have been new rifting and volcanic activity, most notably those associated with the development of the so-called Cameroun volcanic line extending from the offshore islands in the Gulf of Guinea into central Cameroun.

Freeth's presentation appeared fairly convincing in a hand-waving sort of way, or at least it was something worth thinking about. But it failed to convince Thorpe and Wright (*Earth Planet. Sci. Lett.* 42, 327; 1979) who have now objected to it on two main grounds. They point out first that during part of the crucial period up to 40 M yr ago, when the Benue rift was supposedly under membrane compression, the region was actually under net tension — an unexplained inconsistency acknowledged by evidence quoted by Freeth himself. Moreover, during the past 40 M yr, while the region was supposedly under membrane tension as a result of drift away from the equator, it may not have been moving northwards at all. The palaeomagnetic evidence appears to be more consistent with an Africa more or less stationary during this period, an interpretation that opens the way to the alternative hypothesis that "volcanism and tectonic activity are consequences of the focussing of sub-lithospheric thermal anomalies onto a slowly-moving or stationary plate".

The second point made by Thorpe and Wright is that membrane theory postulates peripheral or marginal compressions and tensions in moving plates, a geographical factor that Freeth first acknowledged but subsequently appeared to ignore. The Gulf of Guinea may have been plate-marginal when Africa and South America first separated, but ever since then it has in effect been migrating further into the African plate as the South Atlantic has grown. Nor is the volcanic activity associated with the mid-plate setting of the Cameroun volcanic line unusual in the context of the African continent as a whole; such activity occurs throughout the non-cratonic areas of North Africa and is not even preferentially distributed towards plate-peripheral zones.

A third, rather less central, point made by Thorpe and Wright is that "there is no evidence for any sea-floor spreading and subduction in the Benue trough". This, as students of the region will know, is a highly contentious point. In his response Freeth (*Earth Planet. Sci. Lett.* 42, 329; 1979)

Peter J. Smith is a Reader in the Department of Earth Sciences at the Open University.

devotes considerable attention to it; and if the power of detailed referencing and a sense of conviction were the sole criteria, he would win hands down. It is a pity, though, that in following up this issue Freeth fails to do justice to the two more crucial criticisms. He makes no mention at all of the question of the marginality of compression/tension. Nor does he pursue the problem of compression or tension prior to 40 M yr ago. On the other hand, he does deal with the continental drift issue, pointing out quite rightly that the palaeo-continental maps he used, namely those of Smith (A.G.) and Briden *Mesozoic and Cenozoic Palaeocontinental Maps*, Cambridge University Press, 1977) incorporate the most comprehensive data set available.

So where does that leave West African membrane tectonics? In a highly unsatisfactory state, unfortunately. As far as the impartial observer is concerned, a reading of the current literature on the controversy suggests that the opposing cases are equally good, or rather equally bad. In the credibility stakes Thorpe and Wright have the edge; but that may be because by the very nature of things it is easier to put a spanner in the works than build a nice bit of machinery. The moral is that it would probably be better to look to a less complex area if the aim is to assess the reality or otherwise of membrane tectonics. If the object is to explain the evolution of the West African rift system, on the other hand, someone is going to have to put forward some rather more convincing evidence one way or the other. □

## A diet of worms

from J.E. Sulston and J. Hodgkin

FIVE years ago Brenner published an extensive genetic characterisation of the small free-living nematode *Caenorhabditis elegans*. Largely as a result of his pioneering work, this organism has become the subject of many different lines of research. Last May more than 120 researchers met at Cold Spring Harbor to discuss recent findings in *C. elegans* biology\*.

This animal is a self-fertilising hermaphrodite whose rapid life cycle (3.5 days) facilitates genetic manipulation. Its small size (1,000 µm × 60 µm at maturity) and transparency facilitate the observation of cells *in vivo* and also make possible the use of whole mounts for histology. The subsequent location of defined regions and serial sectioning for electron microscopy are now routine. Development is predominantly mosaic, and because of the small and invariant number of cells (550 at

hatching), the behaviour of cells in the wild type can be defined exactly. The genome is small (haploid DNA content twenty times that of *E. coli*) and estimates of the number of essential genes are low (2,000-4,000).

Perhaps the most important advances reported at the meeting were in the isolation of cloned DNA fragments, in the refinement of genetic methods, and in the characterisation of developmental mutants. With these tools, progress towards analysis of the genes controlling development seems feasible.

S. Emmons (University of Colorado, Boulder) described work on randomly cloned restriction fragments: detectable differences between the Bristol and Bergerac races of *C. elegans* could be demonstrated for 15 % of these fragments, and such fragments can therefore be assigned to particular regions of the genetic map. No differences between germ line and somatic DNA were detected for 50 different fragments although such differences (chromatin diminution) are known to occur in certain other nematodes. Analyses of ribosomal DNA (J. Files, Boulder) and of three tRNA genes (T. Tranquilla, MRC Laboratory of Molecular Biology, Cambridge, UK) were reported; the repeat length of the ribosomal DNA is short (6,800 base pairs).

Muscle assembly can be studied both biochemically and genetically in *C. elegans*. A MacLeod (Cambridge, UK) has cloned a cDNA fragment corresponding to the major myosin heavy chain species. The structural gene for this protein, *unc-54*, has been subjected to detailed genetic analysis by R. Waterston (Washington University School of Medicine, St Louis), who presented a fine structure map, and by P. Anderson (Cambridge, UK), who has obtained more than 100 new *unc-54* mutations by a selective technique. Some of these mutations are small deficiencies that allow mapping of the genes adjacent to *unc-54*.

At least 17 other genes affecting the body wall muscle structure are now known, which map throughout the genome (J. Zengel, Baylor College of Medicine, Houston; Waterston, St Louis). Fine structure maps of two of these genes, *unc-15* and *unc-22* were presented by A. Rose and D. Moerman (Simon Fraser University, Burnaby): *unc-15* is the structural gene for paramyosin, but the product of *unc-22* is unknown. It may interact with the *unc-54* (myosin) product since some *unc-54* mutants suppress some *unc-22* mutants. This suppression appears to be specific. On the other hand, two pleiotropic suppressors, *sup-5* and *sup-7*, have been identified that suppress mutations in a wide variety of genes (Waterston and others). Only null alleles appear to be suppressed, and the mechanism of suppression may well be translational.

E. Schierenberg (Max Planck Institute for Experimental Medicine, Göttingen)

reported progress in defining the complete embryonic cell lineage; this has now been described up to the 220 cell stage, and some lineages have been followed considerably further. The Göttingen group has also begun to characterise temperature sensitive lethal mutants that alter embryogenesis at the non-permissive temperature; some of these have abnormalities in the timing of cell divisions and in the movements of embryonic cells. The stages at which development is arrested have been described for these mutants, and also for a set of non-conditional lethal mutations isolated by P. Meneely (University of Minnesota, St Paul). Mutations altering post-embryonic cell lineages have been found: a number which affect vulval development were described by C. Ferguson (Massachusetts Institute of Technology). In two other mutants certain cells fail to undergo terminal differentiation and continue to divide in a stem cell mode instead (M. Chalfie, Cambridge, UK).

There is increasing interest in the experimental manipulation of development. Isolated blastomeres can now be cultured to the point where intestinal and muscle cells have differentiated (P. Bazzicalupo and J. Laufer, Boulder). The fate of the blastomeres is largely independent of the presence of their neighbours, and after blockade with cytochalasin and colchicine, characteristic intestinal granules develop only in those blastomeres that would normally give rise to the intestine. By both these criteria early development is mosaic. On the other hand, definite episodes of regulative development after hatching have been demonstrated by cell ablations with a laser microbeam (J. Kimble, Cambridge, UK) although here too development is predominantly mosaic. In further analysis of these events cell specific markers will be of great importance. Suitable probes are cloned cDNA preparations which can be used for *in situ* hybridisation to mRNA (K. Edwards, Boulder), antibodies to specific cell products (M. Klass, Boulder), monoclonal antibodies (Y. Argon, Carnegie Institution, Baltimore) and plant lectins (E. Hedgecock, Cambridge, UK).

Many other investigations were reported at the meeting but cannot be described here in detail, including work on ageing, cuticle structure, dauer larva formation, egg laying, fertilisation, hormones, intermediary metabolism, neuropharmacology, nutrition, sex determination, sperm motility, and tail formation. There were relatively few presentations on the neurobiology of *C. elegans*, although almost all of the wild type neuroanatomy has now been reconstructed. Work on the related but much larger nematode *Ascaris* was reported by J. Donmoyer and J. Walrond (University of Wisconsin, Madison); the organisation of the ventral

\*The Second International *Caenorhabditis elegans* Meeting, supported by the US National Institute of Aging and National Science Foundation was held on 10-13 May 1979.

J.E. Sulston and J. Hodgkin are staff scientists at the MRC Laboratory of Molecular Biology, Cambridge, UK.

cord neuroanatomy appears to be similar in the two species, and electrophysiological experiments (impossible in *C. elegans*) have led to the formulation of a model for bend formation in *Ascaris*. The same two classes of acetylcholinesterase are found in both nematodes, and both are widely distributed in *Ascaris* (C. Johnson, University of Wisconsin, Madison). The elimination by mutation of the two classes (but not either class alone) leads to defective movement in *C. elegans* (J. Culotti, Göttingen).

The participants seemed to be united in their enthusiasm for *C. elegans*, and their interest in all aspects of its biology. Specialisation has not led to fragmentation. □

## Nonsolar planets and their detection

from David W. Hughes

I AM never sure which is the more surprising supposition — that our planetary system is of such extreme rarity that it might be unique in the Galaxy — or that planetary systems similar to ours exist in orbit around one in every four stars. There seems to be no inherent reason why Earth should not be the only home for living creatures, an assumption that obviously makes our search for extraterrestrial life futile. On the other hand planets may well be common. There seems to be no sharp distinction between binary and multiple star systems and stars with planetary companions. The masses of small stars in binary systems seemingly grade continuously down to the masses of planets. The obvious solution to this dilemma is 'look and see'. The discovery of nonsolar planets would provide a vital clue to the origin of the solar system, a subject which is bedevilled at the present by the fact that only one solar system can be studied in detail. Bracewell and MacPhie have reviewed the problems inherent in searching for nonsolar planets in a recent edition of *Icarus* (38, 136; 1979).

Astrometry is one of the existing techniques which, according to the authors, "with sufficient refinement may detect nonsolar planets". Plate scales of 15 arc sec per mm can be obtained with very long focus refracting telescopes and these enable very small angular displacements of stellar images to be detected. A year's observation gives a precision of 0.003 arc sec. The problem is exemplified by the fact that an observer of the Sun from a distance of 10 parsec would be looking for an epicycloid wiggle of amplitude about 0.0005 arc sec and period of about 12 yr just to detect Jupiter. Needless to say, many researchers regard the astrometric technique as already sufficiently refined to detect planets. Van de Kamp and

Lippincott of the Sproul Observatory have reported the discovery of invisible planets around Barnard's star, Epsilon Eridani and Ci 2354. Lalande 21 185 is also thought to have a planetary companion. It is interesting to note however that unlike the near circular orbits of our planets these objects seem to have high eccentricities, a factor they have in common with double stars.

Orbiting planets can also produce a sinusoidal variation in the stellar radial velocity. Observed in the ecliptic plane and from a distance, the amplitude of the variation for the Sun is  $12 \text{ ms}^{-1}$ , equivalent to a  $3 \times 10^{-5} \text{ nm}$  shift in the 656.28 nm Fraunhofer line of the solar spectrum. Present practice achieves a precision of several hundred metres per second so this is a technique for the future.

When the combined light of Jupiter and the Sun is viewed from say 10 parsec only about one in  $6 \times 10^8$  photons received actually comes from Jupiter. Also light from the Sun, diffracted by the edge of the telescope aperture obscures the planetary light. Diffraction may be overcome by shading the aperture, a process known as apodisation in which light transmission falls off gradually from the centre of the field towards the edge. Such a telescope, in orbit above the atmosphere can theoretically detect planets.

Infrared long baseline interferometry can be used. Planetary thermal infrared radiation might not be strong but at least it comes from near the peak of the spectral distribution. For stars, the infrared spectral region is well down from the peak of the spectrum. The ratio between stellar power and planetary power drops to around 5,000 at wavelengths longer than about  $20 \mu\text{m}$ . As the distance between the elements of an interferometer is increased, fewer and fewer objects can be detected. The ones that can are those with the smallest angular diameter and this of course favours planets. Bracewell and MacPhie consider possible infrared observations that can be obtained by future space probes. The first one entails having two orbiting infrared ( $40 \mu\text{m}$  say) collectors separated by 44 km (that is  $10^9$  wavelengths). The angular diameter of the star is then about five times the interference fringe spacing so as the star changes its position relative to the fringe pattern the receiver power hardly varies. The planet however is about one tenth the stellar angular diameter and fringes sweeping over the planet produce a substantial modulation. Unfortunately the observing advantage gained is only about 20, which does little to reduce the previous factor of 5,000.

An improvement can be made by placing a minimum of the interference pattern on the star. The planet is then placed at the

adjacent maximum, this requiring, at  $40 \mu\text{m}$ , a base line of 7.7 m for an angular separation of  $2.6 \times 10^{-6} \text{ rad}$  between star and planet. The star to planet power ratio drops to an amazing 1/80. This signal can be modulated, and thus more easily detected against the background, by spinning the interferometer about an axis through the star. Unfortunately the basic pointing accuracy required is 0.001 sec arc. For a detector of area  $1 \text{ m}^2$  and a receiver of bandwidth  $\Delta\lambda$  equal to  $0.1\lambda$  a planet like Jupiter 10 parsec away would produce a flux of 2 photons per second. A reasonable signal to noise ratio is obtained with 10 h of observing time. Unfortunately again, the particles that scatter the zodiacal light produce a strong infrared background and the proposed detector would register 150 photon  $\text{sec}^{-1}$  from this source. To measure the planetary signal against this large background to an accuracy of a few per cent would take a month.

The device proposed by Bracewell and MacPhie has two off-axis paraboloids producing the interference null. Tracking control uses the interferometer optics but at visual wavelengths, the infrared and visual beams being separated by 45 degree plates. The critical components of the detector will be kept at liquid or superfluid helium temperatures, less critical parts having to make do with the 30 K temperature of the triple point of neon.

Obviously this instrument is utilising all the hoped-for technical improvements. It is also apparent that all our attempts to detect non-solar planetary systems rely so far on the observation of minor fluctuations in large quantities. We will have to wait a long time before we get a high definition view of another solar system, an agonising wait which does little to stifle our feeling of loneliness in the universe. □

## Reconstructing the past

from Peter D. Moore

IT is the task of the palaeoecologist to make mental reconstructions of past environments on the basis of such evidence as assemblages of fossils. First the assemblage must be interpreted in terms of contemporaneous communities of organisms; second, the environment is reconstructed from what is known of the ecology of the organisms involved. The Quaternary palaeoecologist would seem to have certain advantages at both these interpretive stages as most of the species with which he deals are still extant and can therefore be subjected to various types of community analysis and other types of ecological enquiry. Just how real these advantages are may be questioned, for

David W. Hughes is a Lecturer in the Department of Physics, University of Sheffield.

many problems of interpretation remain at both levels of analysis.

These problems are well illustrated by the current concentration of attention on the closing phases of the last glaciation. Of particular interest is the climatic event which took place between about 11,000 and 10,000 yr ago, which involved the reversal of the trend towards increasing warmth and deglaciation, and resulted in the re-advance of glaciers in Scandinavia and Scotland and the reformation of local corrie glaciers in outlying mountainous districts. This event (often referred to as the 'Younger Dryas' after the discovery of remains of the plant species *Dryas octopetala* within sediments where the episode was first described), was very localised on a global scale.

Some views of the conditions prevailing during these times were expressed at a meeting of the Quaternary Research Association at University College, London in January. W. A. Watts (Trinity College, Dublin) showed that the biological changes induced by the event were pronounced and of both qualitative and quantitative character in the maritime fringes of North-West Europe, as in the western British Isles, but were weaker and became increasingly difficult to detect in fossil assemblages as one moved eastwards and southwards across Europe. In the area of the Alps there are only small, quantitative changes in flora during the Younger Dryas together with some sediment changes indicating increased erosion. South of the Alps, in the Po Valley, there are no sediment changes and the entire event is difficult to detect on the basis of the pollen record.

Such geographical variations in the fossil record of the time illustrate the local nature of some apparently profound climatic changes. In the case of the Younger Dryas event, it suggests that the climatic cause was associated with oceanic air or water masses, and Watts drew attention to the marine sediment evidence of a more southerly location of the Polar water mass front in Younger Dryas times.

Having established the geographical and temporal pattern of this climatic deterioration, one is then faced with the question of the precise sequence and nature of climatic conditions within its span.

Evidence from benthonic ostracods was presented by J.E. Robinson (University College, London) for the shelf waters of North-West Europe. Here the Younger Dryas event is marked by a decrease in species richness, which is now a characteristic of Arctic waters, and also by the occurrence further south of ostracod species now restricted to the Arctic Ocean, such as *Rabulimys mirabilis* and *Krithe glacialis*. This use of indicator species is an interpretive technique commonly used by palaeoecologists, which is based on the assumption that the factors which determine current distribution patterns of extant organisms are the same as those

which limited their distribution in the past. In this case temperature is thought to be the critical limiting factor. Although attractive as a rule of thumb, there are several problems associated with the use of this line of reasoning. Most physical environmental factors are complex in their diurnal and seasonal variations and it is only rarely that one can pinpoint the interaction between such a factor and the life history of an organism which results in the limitation of the organism's range. Also, such relationships are often made complex by the involvement of other species, such as prey, predators, parasites and competitors. Because such communal relationships can vary in time, the physical factors currently coinciding with an organism's range may not have so coincided in the past.

This is certainly not a problem confined to ostracods. Work on beetles presented by G.R. Coope and M. Joachim (University of Birmingham) has the same interpretive difficulties. They examined fossil assemblages of beetles from sediments at St Bees, Cumbria, which just predate the Younger Dryas. They showed a sequence of species moving from those with present distributions of a southern European type (occurring before 12,000 yr ago) to those with present ranges restricted to northern Scandinavia (occurring after 11,600 yr ago). They point out that, although this suggests increasing coldness of climate, two facts make precise climatic interpretations difficult. First, there are no modern equivalents of these beetle communities and, second, in times of rapid climatic fluctuation, as these undoubtedly were, stable communities in which competitive sorting had taken place were never established.

The plant fossil record is equally subject to these problems. J.B. Macpherson (Memorial University of Newfoundland) attempted an analysis of Younger Dryas climates on the basis of certain indicator pollen types. At a kettlehole site in the Spey Valley, Scotland, she found a pollen sequence in Younger Dryas sediments which led from an *Empetrum* maximum, through an *Artemisia* maximum, back to a further *Empetrum* peak. Together with evidence from sediment stratification, she interprets this as indicating a climatic sequence of oceanic, high snowfall, through continental, low precipitation, back to oceanic once again.

*Empetrum* was long ago used as an indicator of oceanicity by Jessen (*Proc. R. Ir. Acad. B* 52, 85; 1949) and its value in this respect has been discussed at length by Brown (*New Phytol.* 70, 841; 1971). The argument is based entirely on the present range of the genus and experimental data are lacking. Its modern distribution is complicated because it is found in continental areas (for example, Siberia), where it occurs mainly under coniferous forest canopies. It survives in sites of low winter temperature if there is adequate snow-lie. Many species of *Artemisia* do

have more continental distributions, but it is a large and ecologically varied genus and the assignment of a blanket 'continental' label is undoubtedly an oversimplification. It is not impossible that the balance between *Empetrum* heath and *Artemisia* herb communities could be determined by a factor such as wind speed and frequency, which would affect snow-lie.

W. Pennington (University of Leicester) reported the results of a quest for present-day equivalents of the lost plant assemblages of the Younger Dryas. European sites have proved of limited value because of the current high latitude extension of forest due to the oceanic influence of the Gulf Stream drift. Greenland, on the other hand, has very restricted forest and hence is a more likely site for the existence of plant communities resembling those of the late-glacial in their pollen rain spectra.

The coastal fringe of western and southern Greenland has a low rainfall (100-250 mm) and, growing on bare patches of soil, *Artemisia borealis* is locally frequent. The surface lake sediments from such areas have up to 4 or 5% *Artemisia* pollen, which approximately corresponds to the percentage cover of the plant in the catchment area. These values are similar to those found in Younger Dryas pollen assemblages in northern Scotland.

A recently published pollen diagram from Loch of Winless in Caithness, North-East Scotland by Peglar (*New Phytol.* 82, 245; 1979) has about 2-3% *Artemisia* during the presumed Younger Dryas, which falls to zero with the commencement of the Holocene (Flandrian). At the transition there is a peak of more than 5% *Empetrum*. If this diagram is compared with that most recently published from North Wales, Melynlyn in Snowdonia by Walker (*New Phytol.* 81, 791; 1978), a very similar sequence is found. *Artemisia* attains about 5% in the Younger Dryas and there is an expansion of Ericales (undifferentiated) at the opening of the Holocene. Evidently the changes of climate occurring over a short period at that time were more profound than those climatic differences between the two sites resulting from geographic, spatial factors at any given time.

The conclusion one must draw from these examples is that we are still far from being able to make precise statements concerning the climate of the Younger Dryas on the basis of biological evidence. The use of indicator species, even if adequate autecological information is available, can be misleading unless taken in the context of total assemblages. And the interpretation of whole assemblages is frustrated by the lack of precise present-day equivalents. □

## Meteorology of the Indian summer monsoon

**D. Cadet**

Laboratoire de Météorologie Dynamique du CNRS Ecole Polytechnique, 91128 Palaiseau Cedex, France

*The seasonally varying monsoon circulations associated with the annual heating and cooling of the Asian continent are the most important large-scale aspects of the general circulation of the atmosphere. The Indian summer monsoon affects the lives and the economies of many countries in Asia. The study of this phenomenon has been mainly limited to the Indian subcontinent whereas it takes place over the entire Indian Ocean. The lack of information over the marine region will be removed this year during the first Global Atmospheric Research Programme Global Experiment with the implementation of the Monsoon Experiment (MONEX) observational programme.*

THE term monsoon has been used to describe the biannual complete reversal in the prevailing wind flow in the lower atmosphere over the Indian Ocean. The reversal of the air flow is mainly a consequence of the distribution of land and ocean characterised by a large continent in its northern part and a large ocean in its southern part (the topography is also important). The monsoon (south-west during the summer and north-east during the winter according to the direction of low-level flow) is primarily caused by differential heating between the continental areas and the oceans as a result of the zenithal march of the Sun. This was recognised in 1628 when Edmund Halley proposed that the monsoons of South Asia result from differential heating of land and sea surfaces. In 1921, Simpson<sup>1</sup> supported this hypothesis but also emphasised the role of the Himalayas.

The term monsoon does not, however, only apply to the wind regimes prevailing over the Indian Ocean, it also describes the phenomenon in the tropical and equatorial regions of Africa and South Asia. The Asiatic summer monsoon is the best known monsoon region, probably owing to the associated rainfall. Here the term monsoon refers to the rains which fall during the June–September period, although mariners usually associate the monsoon with winds.

### The burst of the monsoon

As the Sun moves northwards bringing spring to the Northern Hemisphere, heat lows begin to form over the continental regions surrounding the Arabian Sea in May. A trough of low pressure forms and extends from Somalia northwards across Arabia and into the principal heat low located over Pakistan; this low-pressure belt extends northeastwards into central India. By the end of May, the heat lows have become well established and the south-west monsoon flow spreads northwards over the Arabian Sea, India and the Bay of Bengal. This change in the lower troposphere occurs quite abruptly and simultaneously over all the Indian Ocean: within a few days the intensity of trade winds of the Southern Hemisphere increases and the cross-equatorial flow becomes established<sup>2</sup>. The rainfall is not synchronous with the dynamical changes. In a rainfall orientated

definition of the monsoon, the south-west monsoon sets in during late April and early May in Burma. The rainbelt then advances northwestwards over a broad latitudinal area reaching the Coromandel coast towards the end of May and the Thar Desert in early July (Fig. 1). This rain belt can be associated with the northwards motion of the ITCZ located over the head of the Bay of Bengal during the winter months. The advance is unsteady and is not evenly paced. At Delhi, for instance, the average date of monsoon arrival is 2 July, but between 1901 and 1950 the actual dates ranged from 17 June to 20 July, with a standard deviation of 7.8 days. The rainfall is so sudden and spectacular that it is known as the burst of the monsoon.

The upper air circulation also undergoes an abrupt change in the entire Northern Hemisphere. At the end of May, an elongated warm belt appears between the Arabian Desert and southwestern China along 28° N in the mid-troposphere. The westerly southern jet moves downstream into China and dissipates; it is replaced by an easterly jet. This jet appears first over the Bay of Bengal and expands eastwards to the Philippines and westwards to Africa. The mid-tropospheric anticyclone established during the pre-monsoon season disappears in June and is replaced at about 80° E by the upper trough moving from the Bay of Bengal. Over northern India and nearby, two anticyclones come into existence in June; one over the Thar Desert

Fig. 1 Average onset dates of the rainy season (from ref. 57).

**Fig. 2** July mean sea level isobars (mbar) (from ref. 58). The mascarene high pressure over southern Indian Ocean, the monsoon trough over India and the equatorial trough to the east of 70° E can be seen.

(above 700 mbar) and another over southern Tibet (above 500 mbar).

These changes in circulation patterns that take place in June are many and varied, and meteorologists have tried to relate the changes to the burst of the monsoon. Some have related the advance of the monsoon with the shift of the upper trough and the westerly jet and the development of the easterly jet<sup>3</sup>. Other meteorologists think the burst takes place when the air from the Southern Hemisphere goes into the circulation over the subcontinent<sup>4</sup>. In fact there seems to be no cause-effect relationship between the development of the circulation in the lower and upper levels, the insolation and the influence of topography being prominent in both cases. Another closely related question is what determines the year-to-year variations in the date of the onset of the monsoon.

### Climatology of the Indian summer monsoon

As we have seen, certain elements are established over the Indian subcontinent during the pre-monsoon months. However, the Indian summer monsoon must be seen as a broad-scale system and it also includes components in the Southern Hemisphere. For a complete picture of the phenomenon all these elements must be described.

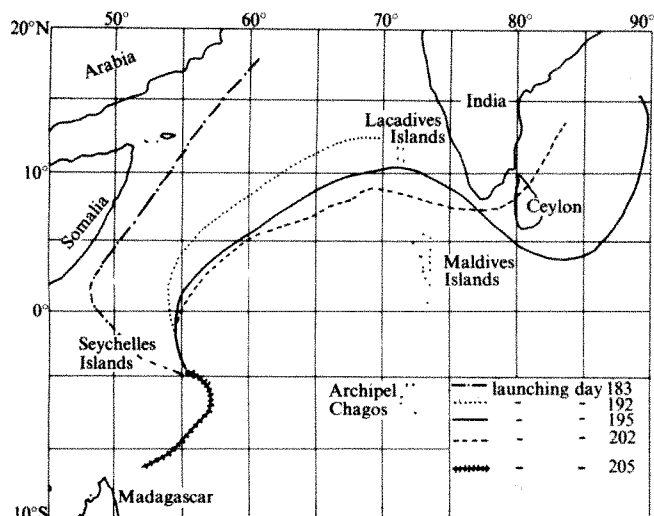

The monsoon trough over northern India is a very prominent feature of the synoptic weather charts during the summer season (Fig. 2). It is a part of the global equatorial trough of the northern summer season and indicates the separation between air of Northern and Southern Hemisphere origin<sup>5</sup>. It lies parallel to and about 450 km south-west of the Himalayas and is probably topographically anchored. The southwesterly to westerly air current from the Arabian Sea and the deflected air current from the Bay of Bengal meet along the Gangetic Valley giving rise to this trough which is connected to the Pakistan heat low. The topographical features of the subcontinent play an important combined dynamical and thermodynamical role in the location of the heat low and the development of the Gangetic Valley trough. The Himalayas force the monsoon current to ascend and thereby release latent heat. Thus, the mountains contribute significantly to making the monsoon circulation self-sustaining in the lower levels of the atmosphere and the Indian monsoon circulation different from monsoons in other parts of the world. The influence of topography on the streamflow also extends to higher levels. The heat low extends to above

850 mbar while the trough extends to about 500 mbar. Above 500 mbar the westerly and easterly flow is associated with the Tibetan anticyclone, to the north of 27° N, which has its maximum amplitude near 200 mbar.

Over the Arabian Sea the low-level flow from the Southern Hemisphere is the main characteristic of the monsoon. There has been controversy about the origin of the southwesterly winds<sup>6</sup> although recent experiments have demonstrated that these winds effectively correspond to the south-east trades of the Southern Hemisphere deflected after crossing the Equator, by the Coriolis force and the Southern Hemisphere trough located around 80° E on the Equator. This was shown by the measurements of radioactivity over the Arabian Sea which allows us to separate land and marine air<sup>7</sup> values. Another set of measurements was given by lagrangian trajectories of constant-level balloons flying in the boundary layer and launched from the Seychelle Islands (Fig. 3)<sup>8</sup>. The cross-equatorial flow is not uniform at all longitudes; it is weak in the eastern Indian Ocean where it enters the Bay of Bengal, and is strong along the East African coast (Fig. 4)<sup>9</sup>. Associated with the Southern Hemisphere trough on the Equator are weak westerlies found around 80° E and 5° S. Along the Somali coast, the air flow is characterised by one of the most intriguing phenomena of the monsoon: the low-level Somali jet which is in fact a major part of the southwesterly flow to the Indian continent (Fig. 5a and b)<sup>10</sup>. This low-level current, most pronounced at heights of 1–1.5 km, flows from the ocean near Mauritius over the northern tip of Madagascar to reach the Kenya coast at about 3° S. It then penetrates inland over the flat low-lying eastern areas of Kenya, Ethiopia and Somalia to reach the coast again near 9° N and then swings across the Arabian Sea to India. It splits into two parts over the sea, the more northern branch intersecting the west coast of India near 17° N while the southerly branch moves eastwards just south of India. This jet is occasionally reinforced or even temporarily replaced by a stream of air moving northwards up the Mozambique channel. The maintenance of the jet and its periodic fluctuations in strength are not well understood. A recent study using geostationary satellite images to determine the low-level air flow from cloud displacements<sup>11</sup>, suggests that the variation in strength (occurring with a quasi-biweekly period) result through the influence of cold fronts at mid-latitudes in the Southern Hemisphere which induce surges in the south-east trades as suggested earlier<sup>12</sup>. Its three-dimensional structure was studied in 1977 using an instrumented aircraft<sup>13</sup>. Jet-speed winds also occur over the central Arabian Sea and the Indian Peninsula in connection with the Somali jet<sup>14</sup>. The problem of the numerical simulation of this jet has been examined<sup>15</sup>. The  $\beta$ -effect, the orographic barriers over East Africa and Madagascar and a broad-scale monsoon forcing over India are some of the crucial elements for a proper simulation. Off the Somali coast, the atmospheric jet passes over the well known area of upwelling cold-coasted water which has also been numerically simulated<sup>16,17</sup>.

The air mass over the Arabian Sea consists of an inversion layer which exists over the flat lowlands of eastern Africa and over most parts of the Arabian Sea, inhibiting the development of deep clouds<sup>18</sup>. The height of the base of the inversion layer, which probably separates the low-level deflected moist trades from drier continental air above, increases eastwards and becomes less marked. The inversion layer disappears east of about 65° E where low-level convergence and ascent in the troposphere favour the dominance of deep clouds and occasional development of monsoon disturbances. How the Western Ghats affect the destruction of the inversion is important<sup>19</sup>. This inversion layer is a control factor in the air-mass modification over the Arabian Sea and can affect the efficiency of monsoon heat engine.

Another important feature of the monsoon system is the upper tropospheric tropical easterly jet near 150 mbar<sup>20,21</sup>. It has winds of roughly 80–100 knots and the strongest winds are found just to the west of the southern tip of India. Its intensity oscillates with a quasi-biweekly period (phase of generation and

**Fig. 3** Trajectories of constant-level balloons at 900 mbar, launched from the Seychelle Islands in 1975 (from ref. 8). Days are 1975 Julian days. The trajectory going towards Madagascar corresponds to a local reversal of the monsoonal flow due to the westward propagation of a tropical disturbance near 10° S (ref. 59).

degeneration early noticed by workers) and it must be seen as a part of the global upper air circulation in the tropics<sup>22</sup>. A numerical model of the broad-scale monsoon system with a few additions can simulate many of the well known broad features of the monsoon and particularly the easterly jet<sup>23</sup>.

It seems difficult to define limits of the monsoon circulation. Reversal of flow in zonal and meridional direction from lower to upper tropospheric has led some authors to suggest a closed circulation. The inflow and outflow from the monsoon area are linked through the general circulation in other areas. With the advent of summer, an east-west Walker circulation with ascent over north-east India and descent over the Pacific and a north-south meridional circulation with ascent over north India and descent over equatorial regions are set up<sup>24</sup>. The conditions in which the Walker circulation changes its intensity and location and the way in which it interacts with the monsoon circulation are largely unknown.

### Monsoon depressions

Monsoon depressions are an important component of Indian weather and have been studied for several years. About 1-3 depressions form per month during the monsoon months, particularly in July and August. These depressions begin to be seen over the Bay of Bengal where satellite photographs show cloud clusters. They do not acquire hurricane intensity during the summer months, because they are not long over the oceanic areas before landfall and the large-scale vertical wind shear over the troposphere inhibits local accumulation of the latent heat release over the disturbance. Heavy rainfall associated with these depressions is the most outstanding associated phenomenon. Up to 300-400 mm of rain in 24 hours have been recorded. The structure of these perturbations has been studied from observations made once the depression has moved over central India where some upper air observations are available<sup>24,25</sup>. The composite structure has also been studied<sup>27</sup>.

The depression is an intense low-pressure system with a vigorous associated circulation; winds of up to about 50 knots have been noted (Fig. 6). Whereas the typical horizontal scale of the depression is known to be around 500 km in the formative stage, it is typically 1,500 km over land. The disturbance has a cold core with its vertical axis tilting eastwards with a slightly warm core above. The maximum rainfall rates occur to the west of the depression. The perturbation is confined to the lower troposphere from the surface up to 400 mbar. The strongest

activity is concentrated in a narrow vertical tube ahead of the depression, characterised by strong cyclonic activity, convergence and upward motion. Relatively weak activity is found behind the depression where anticyclonic vorticity, divergence and subsidence are noted. Case studies indicate that the disturbance is imbedded in a region where the conditions necessary for the combined barotropic-baroclinic instability to exist are satisfied. Monsoon depression is primarily maintained by cumulus convection. The cumulus convective heating generates eddy-available potential energy by releasing heat at appropriate levels above the cold core. Here the rising of relatively warm air contributes significantly to the generation of eddy kinetic energy of the depression.

Whereas early studies suggested *in situ* formation in the Bay of Bengal<sup>28</sup>, recent analyses have led to a proposal of scale interactions of westward moving wavetrains. Such an interaction gives rise to a westward propagating downstream amplification<sup>29</sup>.

Mid-tropospheric cyclones are also an important part of the south-west monsoon. They can be found in the northeastern part of the Arabian Sea and in northern Bay of Bengal. They are known either to move very slowly westwards or remain quasi-stationary for many days<sup>30,31</sup>. The scale is of the order of about 3,000 km horizontally and 5 km vertically. Their largest amplitude is near the 600 mbar surface and they appear as a closed cyclonic circulation generally in the middle troposphere. They usually have a pronounced warm core above the middle level and a slightly cold core below that level. They are usually characterised by very intense convective and non-convective rainfall rates: total rainfall amounts of the order of 20 cm per 24 h can be noted. Flows near the surface and at the 200 mbar level do not show closed circulation. Despite case studies, detailed analysis of these depressions as well as numerical studies are necessary for a clear understanding of the development mechanism of the mid-tropospheric disturbances over the entire monsoon region.

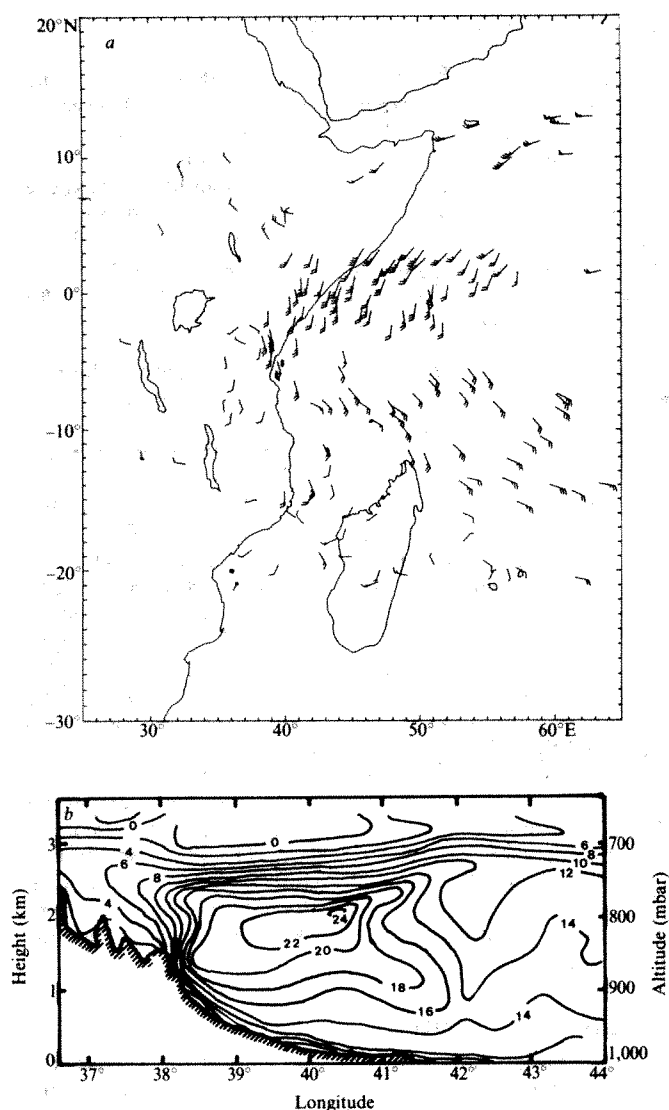

### The monsoon rains

A rapid build-up of atmospheric moisture over India augers the beginning of its monsoon season. Precipitable water vapour increases nearly twofold from March to June<sup>32</sup> and this high water-vapour content of the monsoon air is largely responsible for the heavy rainfall in the summer. The summer rainfall is the main component of the annual rainfall over the subcontinent except in Kashmir and the extreme south of the Peninsula and the east coast area: nearly 80% of India's total annual rainfall falls during the months June to September<sup>33</sup>. The orographic

**Fig. 4** Wind field over the Indian Ocean on 14 July 1975 as determined by an objective assimilation of ship reports (from Cadet and Reverdin, personal communication). The length of the arrow is proportional to wind intensity.

**Fig. 5** *a*, Low-level wind vectors determined from cloud displacements on 23 July 1978 inferred by METEOSAT pictures (from ref. 11); *b*, vertical and longitudinal structure of the meridional (southerly) wind component along the Equator on early morning of 4 July 1975 (from ref. 13).

influence for producing strong convergence in the lower layer is important in the distribution of rainfall. The west coast of India receiving the southwesterly flow and the Burma coast affected by the Bay of Bengal branch of the monsoon receives considerably more rain than the lee-side of the Western Ghats and Burma Mountains. The important rainfall over central India is largely due to the influence of the depressions moving from the north Bay of Bengal and to some extent due to convergence at the trough and the southwards slope of the trough axis with height. The only region contrasting with the common view of heavy rains is the Thar Desert in the western half of northern Indo-Pakistan. The presence of the air mass inversion between the lower shallow moist current (about 800 mbar) and upper drier air mass<sup>34</sup> causes less rainfall in this area.

The low-level current over the Arabian Sea originates in the Southern Hemisphere. However, the origin of moisture contained in this southwesterly flow is still questionable. A large part of the moisture available over the Indian subcontinent is supplied by the Arabian Sea branch of the monsoon. Over India the major water-vapour influx takes place across the Trivandrum-Bombay section, and the layer from the surface up to 700 mbar contributes 86% (ref. 35). The onshore fluxes are well correlated with rainfall along the west coast although a small

fraction is converted into precipitation (13%)<sup>36</sup>. While early estimations led to the conclusion that the contribution from cross-equatorial flow is less than that from the evaporation over the Arabian Sea, further computations have shown the existence of a certain water-vapour influx from the Southern Hemisphere<sup>37</sup>. Some of the flux (30%) into the Indian subcontinent comes from the Southern Hemisphere. The maximum cross-equatorial moisture flux takes place along the East African coast and can be associated with the low-level Somali jet. Observations suggest that some relationship exists between rainfall in India and the Somali jet: increased cross-equatorial flow followed by increased rainfall over western India<sup>10</sup>. However, this question deserves careful consideration<sup>38</sup>. Also, during a drought year the seasonal mean Somali jet is weaker than during a normal year<sup>22</sup>. An appreciable amount of moisture seemed to be picked up over the Arabian Sea. Thus, positive correlations have been found between sea-surface temperature over the Arabian Sea and monsoon rainfall over western and central India<sup>39</sup>. Tests, made with a general circulation model, suggest that rains over India are sensitive to change in sea surface temperature over the Arabian Sea<sup>40</sup>.

Monsoon rains exhibit considerable variations both from one year to the next and within one year (Fig. 7). Thus, the Indian summer monsoon has two basic synoptic patterns: the active and the break (or weak) monsoons. The succession of these patterns gives the well known pulsatory nature to the Indian monsoon which also manifests itself in the wind field. Thus, the monsoonal flow in the lower troposphere (below 500 mbar) undergoes rather drastic changes in association with rainfall variations: during active monsoon periods, a series of disturbances form and move west-northwestward across the Gangetic Plains and rainfall is widespread over the monsoon region. These interruptions, or breaks, last between 3 and 10 days (2–3 weeks in some years), and usually occur between the dissipation of one monsoon depression and the formation of another. During this phase of the monsoon, the monsoon trough shifts to the north from its normal position and heavy rainfall is concentrated along and near the foot of the Himalayas. Low-level westerlies shift north to the Gangetic Plains and in peninsular India they usually weaken and decrease in depth. The upper tropospheric easterlies spread to the north. During such epochs, when the monsoon trough is shifted to the foothills of the Himalayas, a secondary trough forms over the south Bay of Bengal and the south Arabian Sea near the Equator. Thus, there is a well marked negative correlation between the change in cloud density over central India and the equatorial Indian Ocean<sup>41</sup>. Feeble mid-tropospheric lows move from east to west in this trough. The monsoon can be revived under the influence of mid-tropospheric lows moving northwestwards along the west coast of India<sup>42</sup> but there may be other ways of initiating this monsoon sequence<sup>43–46</sup>.

Moisture distribution over the Arabian Sea is different during the two phases of the monsoon. During weak monsoon conditions, the moisture field is stratified whereas this stratification disappears during active monsoon and upwards transport of water vapour occurs. Evaporation seems to be larger during an active spell than during a weak one. During active monsoon, a part of the water vapour obtained by evaporation is transported towards the Indian subcontinent, the other being precipitated over the sea whereas during weak monsoon, the evaporation is used locally in the weather development<sup>47</sup>.

Numerical simulations show that cold sea-surface temperature over the west Arabian Sea leads to a drastic reduction of monsoon rainfall over India because the cold sea decreases the evaporation rate and increases the surface pressure leading to a reduction in the cross-equatorial flow and moisture flux downstream<sup>40</sup>. Thus analysis of a series of sea-surface temperatures over the Arabian Sea shows that during a weak monsoon there is a significant drop in sea-surface temperature over a large area compared with a period of strong monsoon<sup>48</sup>. A numerical simulation experiment of the Somali jet shows that the cross-equatorial flow in the west Arabian Sea intensifies the jet as a

Fig. 6 Sea-level chart on 4 August, 1968 depicting a monsoon depression moving inland from the Bay of Bengal (from ref. 25).

result of the strengthening of the monsoon over India<sup>15</sup>. These and other experiments on the interaction between the Arabian Sea and the Indian monsoon suggest that the strength of the Indian monsoon does not depend on the strength of the cross-equatorial flow; this contrasts with other results that demonstrate a controlling influence of the Somali jet on the monsoon.

Active and break monsoons should be viewed as part of the fluctuations occurring on a very large scale and the changes in circulation of the Indian subcontinent might result from distant effects. Synoptic patterns have to be found which could characterise a break and an active monsoon<sup>49</sup>. The partition of the monsoon into two phases may be compared with the quasi-biweekly oscillation of the broad-scale monsoon elements. The two-week period may be divided into an active and a less active one and our study suggests an interesting ordering of the phase of the various elements of the monsoon system<sup>22</sup>. In fact, no unique or detailed description exists for active and break monsoon and numerical simulation may be useful for understanding the phenomenon and for separating the effects of the different synoptic components.

Long-term variability of monsoon rainfall has been studied in some detail by Indian workers. Quasi-biennial oscillation (QBO) in rainfall has been found at several stations in India<sup>50</sup> as well as in the annual rainfall in some meteorological subdivisions of the country and the monsoon rainfall as a whole<sup>51</sup>. Recent investigations using data of ISMEX-73 indicate that certain interactions exist between QBO and sea-surface temperature and monsoon currents in the equatorial area of the Indian

Fig. 7 Daily rainfall over central India (75°–85° E to 15°–25° N) during a drought year (1972) and a near-normal rainfall year (1973) (from ref. 22).

Ocean<sup>52</sup>. This result suggests that there is some interaction between the circulation in the tropical stratosphere which exhibits the well known QBO for zonal winds. There does not seem to be a significant relationship between Indian monsoon rain and solar activity<sup>51</sup>.

### The retreat of the monsoon

The monsoon in the Indian subcontinent begins to withdraw in mid-September when the circulation pattern in the Northern Hemisphere changes from a summer to a winter regime. The weakening of the easterlies, the southward shift of the monsoon trough and the appearance of the westerly jet stream in northern India are all reversals of the events that occur during the burst of the monsoon. In a year when a break takes place in September, the monsoon may retreat prematurely. The equatorward-motion of the ITCZ (inter-tropical convergence zone) brings abundant rainfall during the retreat of the monsoon<sup>53</sup>.

### Numerical simulation

The main objective of monsoon studies is to improve the ability to predict the atmospheric motion and associated rainfall over Asia. Empirical attempts have been made to predict, for example, the onset of the monsoon from wind activity over the Arabian Sea<sup>54</sup> or rainfall of western India from surges and lulls in the cross-equatorial flow<sup>55</sup>. Studies made to determine dynamical and thermodynamical structure of the atmosphere during break and active monsoon have been tentatively used to predict the occurrence of these different phases of the monsoon.

The development of numerical simulation is at an early stage but will be activated after the results of the Monsoon Experiment in 1979. Different types of numerical models can be developed. Specific regional fine-mesh models can be used to study certain components of the monsoon such as the Somali low-level jet, Bay of Bengal depression and mid-tropospheric disturbances. Global models with nested fine-grid system must be used to determine the conditions under which monsoon circulation interacts with the global circulation. Predictability experiments are urgently needed to investigate the feasibility of numerical weather prediction over the monsoon region for developing numerical prediction models.

### The experimental programme to study the Indian summer monsoon

For a long time, observations have been confined to the Indian Ocean although their deficiencies were recognised. The Indian Ocean is so large that international cooperation is necessary to make marine observations. An international experiment, the International Indian Ocean Expedition (IIOE), was conducted in 1963–64 and produced a large amount of information about the development of the monsoon over the Indian Ocean<sup>56</sup>.

The idea of a special monsoon experiment to be conducted during the First GARP Global Experiment (FGGE) was proposed in 1971. This idea was developed through two experiments: ISMEX-73 and MONEX-77. ISMEX-73, conducted by USSR and India, took place between 15 May and 10 July 1973. MONEX-77 took place during the summer of 1977 for the study of the Indian summer monsoon, and the winter of 1977 for the study of the winter monsoon over the Malaysia–Indonesia region. These two limited experiments considerably increased our knowledge of the development of the monsoon over the Indian Ocean and the structure of some monsoon elements (monsoon depressions and Somali low-level jet). They prepared the way for the main experiment to be conducted in 1979.

The main experiment, MONEX-79, has two components: the winter monsoon and the summer monsoon. The winter monsoon was conducted during the First Special Observing Period (SOP I) of FGGE (15 January–15 March). The summer monsoon will take place from May to September with an intensive period during SOP II of FGGE (May–June)<sup>57</sup>. The

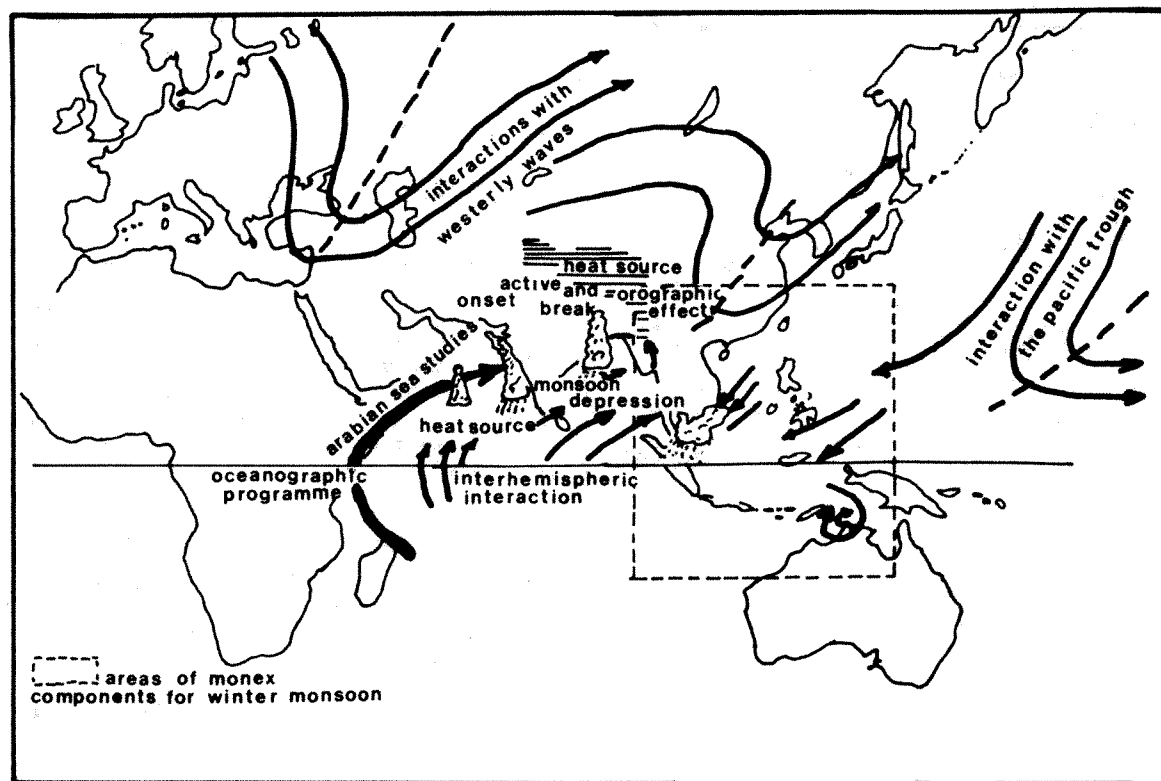

Fig. 8 MONEX-schematic illustration of major component programmes (from ref. 57).

summer MONEX can be divided into two phases. The first coincides with the SOP II and, taking advantage of the ship network over this area, will study the development of the monsoon over the Arabian Sea (Fig. 8). Instrumented US aircraft will study the structure of the atmosphere. About 90 superpressure constant-level balloons will be launched by a French group from the Seychelle Islands and Diego Suarez (Madagascar) to fly in the tropical boundary layer. The balloons tracked by the TIROS-N satellite will provide, along with their positions, recordings of pressure, temperature and moisture at flight level. This experiment will complement the boundary layer data by giving lagrangian trajectories of the mixed layer over the ocean. At the beginning of July the ships will move to the Bay of Bengal for the second period to study monsoon disturbances generated over this region. For the entire period (May to September), the surface synoptic network has been strengthened. Commercial aircraft and ships will enhance the network (especially the aircraft which will provide data on upper tropospheric winds over the ocean). The space-based part of the global observing system will be very important, especially the geostationary satellite over the Indian Ocean (GOES-1) from which winds can be determined by cloud tracers. Thus, with the high resolution geostationary satellite picture adequate low-level winds over the Indian Ocean can be deduced and a daily description of the circulation obtained. An important oceanographic programme will also be carried out during MONEX.

## Outlook

From the MONEX and FGGE data sets obtained in 1979, it will be possible to study the Indian summer monsoon on both a regional and a global scale. Undoubtedly the knowledge of the phenomenon will be improved within a few years. All this information is necessary for the development of reliable numerical models for weather forecasting. Such numerical forecasting of the vagaries of the Indian summer monsoon would benefit the populations of southern Asia. However,

forecasting needs continuous information about the present state of the atmosphere. The large marine extension of the phenomenon means this can only be made on an operational basis by space observatories; hence polar orbiting and geostationary satellites are needed.

## How tidal heating in Io drives the galilean orbital resonance locks

Charles F. Yoder

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California 91103

*Tidal heating in Io is the most likely energy source of its volcanic activity. Tidal dissipation in Io and Jupiter also controls the resonance configuration among the three inner satellites. The formation of the several resonance locks is described in detail in this article. This model sets limits on the Q values of both Io and Jupiter.*

THE Voyager 1 spacecraft fly-by of Jupiter provided startling images of the several active volcanoes on Io. Tidal heating in Io has been identified as a potentially important energy source<sup>1</sup> and it has been suggested that this same mechanism also controls the evolution of several orbital resonance locks among the three inner satellites. This article discusses in more detail how these resonance locks are maintained and describes the effects of dissipative tides in both Jupiter and Io on their establishment and evolution. The most significant results of this study are that the three-body resonance may have formed  $<5 \times 10^8$  yr ago and that a measurement of the rate of tidal heating in Io not only determines, say, the  $Q$  value of Io, but also  $Q_J$  of Jupiter. Arguments are also given which limit  $Q_J$ :  $2 \times 10^5 < Q_J < 2 \times 10^6$ . The factor  $Q/2\pi$  is equal to the ratio of the peak strain energy in each tidal flexing cycle to the energy dissipated per cycle<sup>6</sup>.

The most well known resonance involves the three inner galilean satellites, Io (1), Europa (2), and Ganymede (3). The mean longitudes  $\lambda$  of these three satellites when combined in the following combination:  $\lambda_1 - 3\lambda_2 + 2\lambda_3$  happens to equal an odd multiple of  $180^\circ$ . Lieske<sup>2</sup> found that the libration amplitude of this resonance variable is  $0.066^\circ \pm 0.013^\circ$  and that the period is 2,074 d. The other set of resonance variables involve the near commensurability of the mean motions of the inner pair and the forced precession of their pericentres,  $\tilde{\omega}_1$  and  $\tilde{\omega}_2$ . The mean daily motion of  $\tilde{\omega}_1$  and  $\tilde{\omega}_2$  is  $-0.7395^\circ \text{d}^{-1}$ . Sinclair<sup>3</sup> and Chao<sup>4</sup> noted that the arguments  $\lambda_1 - 2\lambda_2 + \tilde{\omega}_1$ ,  $\lambda_1 - 2\lambda_2 + \tilde{\omega}_2$  and  $\lambda_2 - 2\lambda_3 + \tilde{\omega}_2$  executed small amplitude librations about either 0 or  $180^\circ$ . In fact, it is just the interaction of the last pair of variables which predominately controls the three body couple.

Table 1 contains some of the pertinent physical data<sup>2,10</sup>: mass  $M$ , radius  $R$ , semi-major axis  $a$ , mean daily motion  $n$  and both free forced eccentricities. The free or proper eccentricity

represents that eccentricity which would remain if we could slowly remove all perturbing forces. The libration amplitude of the 2:1 resonance is equal to the ratio of the free to the forced eccentricity.

### Tidal interaction on Io

It is a common misconception that the principal tide on a synchronously rotating satellite moving in an eccentric orbit is radial. This idea can be traced to MacDonald's<sup>5</sup> purely phenomenological model which tried to incorporate the restriction that tidal dissipation in a synchronously locked satellite cannot transfer angular momentum from its spin to its orbit. In reality, the dominant tide moves back and forth across the mean sub-planet point as the satellite moves in its orbit (see Fig. 1). At pericentre, where dissipation and the resultant torque are greatest, the orbital angular motion is  $n(1+2e)$ . As seen from the planet, the satellite seems to rotate retrograde with angular velocity  $\sim -2en$ . Dissipation in the satellite causes a time delay ( $\approx 1/Qn$ ) of high tide leading to a displaced tidal bulge which leads the instantaneous sub-planet point. The torque by the planet acts to spin up the satellite but is prevented from doing so because of the existence of a permanent bulge. The effect of dissipation is to displace the rigid bulge until the resulting torque by the planet exactly cancels the average tidal torque.

The equations describing the evolution of the satellite orbit due to the inelastic planetary and satellite tides are<sup>6</sup>:

$$\frac{1}{n} \frac{dn}{dt} = -c(1 - (7D - 12.75)e^2) \quad (1)$$

**Table 1** Physical data of the three inner galilean satellites

	Io	Europa	Ganymede
$M/M_J \times 10^5$	$4.684 \pm 0.022$	$2.523 \pm 0.025$	$7.803 \pm 0.030$
$n$ (deg per day)	203.4890	101.1747	50.3176
$a$ (km)	422,000	671,400	1,071,000
$e_{\text{forced}} (2:1)$	0.0041	0.0101	0.0006
$e_{\text{free}}$	$1 \pm 2 \times 10^{-5}$	$9 \times 10^{-4}$	0.0015
$R$ (km)	$1,818 \pm 3$	$1,533 \pm 27$	$2,608 \pm 32$

$$\frac{de^2}{dt} = -\frac{2}{3}c(7D - 4.75)e^2 \quad (2)$$

$$D = 2k\left(\frac{R}{R_J}\right)^5 \left(\frac{M_J}{M}\right)^2 \frac{Q_J}{Q}; c_{10} = 6.1 \times 10^{-13} Q_J^{-1} \text{ s}^{-1} \quad (3)$$

For small homogeneous satellites the Love number  $k \approx 3/19 \rho g R \mu^{-1}$  where  $\rho$  is the density,  $g$  the surface gravity and  $\mu$  the rigidity. If Io were lunar-like then  $\mu \approx 6.5 \times 10^{11}$  and  $k = 0.027$ . Incidentally, Jupiter's fluid Love number equals 0.50. The parameter  $D$  is the ratio of the tidal scale factor of Io to that of Jupiter. For Io we find that  $D \approx 1,300$  if we adopt 'plausible' values for  $Q_J = 5 \times 10^5$  and  $Q_{10} = 100$ . We shall argue later that  $D \approx 4,300$ .

Suppose that Io were formed well inside the orbit of Europa about  $4.6 \times 10^9$  yr ago. Any initially free eccentricity in Io's orbit would be quickly damped by Jupiter, and Io's orbit would thereafter expand, driven by the dissipative tide it raises on Jupiter. Europa's orbit would also expand, but because of Io's greater mass and smaller semi-major axis, Io would spiral out faster. Io would eventually approach the 2:1 commensurability with Europa. This near resonant interaction is adequately described by the following set of differential equations<sup>4,7</sup>.

$$\frac{dn_1}{dt} = 3 \frac{M_2}{M_J} n_2^2 \left(\frac{a_2}{a_1}\right)^2 [e_1 C_{11} \sin(V_1 + \tilde{\omega}_1) + e_x C_{21} \sin(V_1 + \tilde{\omega}_2)] + \frac{dn_1}{dt_T} \quad (4)$$

$$\frac{dn_2}{dt} = -6 \frac{M_1}{M_J} n_2^2 [e_1 C_{12} \sin(V_1 + \tilde{\omega}_1) + e_2 C_{22} \sin(V_1 + \tilde{\omega}_2)] \quad (5)$$

$$\frac{dp_1}{dt} = -in_2 \left(\frac{a_2}{a_1}\right)^{1/2} \frac{M_2}{M_J} C_{11} \exp(iV_1) - \left(\frac{7}{3} Dc + i\dot{\omega}_{s1}\right) p_1 \quad (6)$$

$$\frac{dp_2}{dt} = -in_2 \frac{M_1}{M_J} C_{22} \exp(iV_1) - i\dot{\omega}_{s2} p_2 \quad (7)$$

where  $V_1 = \lambda_1 - 2\lambda_2$ . The coefficients  $C_{11} \approx C_{12} = C_1 = -1.18$  and  $C_{21} \approx C_{22} = C_2 = +0.42$  are polynomials in  $a_1/a_2$ . The variations of the pericentre  $\tilde{\omega}$  and eccentricity are most easily described by the variables  $p = e \exp(-i\tilde{\omega})$  and  $q = p^*$ . The parameter  $\dot{\omega}_s$  is the mean precession rate of the orbital pericentre due to the jovian oblateness, satellite interactions, and so on. For Io,  $\dot{\omega}_s = +0.16^\circ \text{ d}^{-1}$ . This term and the tidal acceleration  $f$  Europa shall be ignored in the following discussion—Europa's acceleration is unimportant because the coefficient  $c_2$  is small ( $\approx 0.021c_1$ ) while the ratio  $D_2 \approx 1,000$ .

**Fig. 1** Location of tidal bulge of a synchronously rotating satellite at different points in its orbit. The tide lags behind at pericentre (a) where the orbital angular velocity  $f$  is greatest. The optical libration of the permanent bulge has the opposite phase and is  $2e$  radians behind a point (b) and ahead at point (c).

A solution for the forced motion of  $p$  can be obtained by assuming that  $\dot{V}_1 = \nu_1$  is constant. This approximation is valid as long as either  $\nu/n$  is large compared to  $(eM_1/M_J)^{1/2}$  or the free eccentricity is small compared to the forced eccentricity, both of which happen to hold in this case. We find

$$p_1 = -\frac{M_2}{M_J} \frac{n_2}{\nu_1} \left(\frac{a_2}{a_1}\right)^{1/2} C_1 \exp(iV_1 + \delta) \quad (8)$$

$$p_2 = -\frac{M_1}{M_J} \frac{n_2}{\nu_1} C_2 \exp(iV_1) \quad (9)$$

The mutual perturbation leads to a forced retrograde motion of the pericentres of both orbits. Dissipation in Io induces a phase lag  $\delta = \frac{7}{3} Dc/\nu_1$  in Io's pericentre. This phase lag means that Io is slightly closer to Europa E just after than just before conjunction (see Fig. 2). Thus the torque, when averaged over the conjunction phase, tends to accelerate Europa in its orbit and decelerate Io.

Substituting the above solutions for  $p_1$  and  $p_2$  into the equations (4) and (5) for  $\dot{n}_1$  and  $\dot{n}_2$ , we obtain

$$\frac{dn_1}{dt} = 7cn_1 D e_1^2 + \frac{dn_1}{dt_T} = -cn_1(1 - 14De_1^2) \quad (10)$$

$$\frac{dn_2}{dt} = 14cn_1 D \left(\frac{a_1}{a_2}\right)^2 \frac{M_1}{M_2} e_1^2 \approx -10.3cn_1 D e_1^2 \quad (11)$$

As Io tidally evolves outwards, Io's forced eccentricity increases until it reaches the critical value  $\approx 1/(35D)^{1/2} \sim 0.0026$ . Europa's limiting eccentricity is  $\sim 0.0014$ . Thereafter, the relative outward acceleration of Europa causes its mean motion to be exactly half that of Io. This stable state is maintained until Europa encounters the 2:1 commensurability with Ganymede. The 4:1 commensurability of Io with Ganymede is third order in the eccentricities and represents a considerably weaker interaction. The inelastic tide raised on Europa will repel Ganymede. Still, the acceleration of Europa by Io is so great that Europa's forced eccentricity would have to be at least three times larger than its present value (0.0101) for this mechanism to push Ganymede out so that  $\dot{n}_2 = 2\dot{n}_3$ . Before Europa's eccentricity can be pumped up to this value the 2:1 frequency  $\nu_2 = n_2 - 2n_3$  of the outer pair approaches that of the inner pair,  $\nu_1 = n_1 - 2n_2$ . The vanishing of the difference frequency describes the presently observed three-body resonance.

## Coupling between Europa and Ganymede

The near resonant gravitational couple between Europa and Ganymede can be obtained by indexing the subscripts of (4-7) by one. The resulting distortion in the shape of Europa's orbit by both Io and Ganymede is

$$p_2 = -\frac{M_1}{M_J} \frac{n_2}{\nu_1} C_1 \exp(iV_1) - \frac{M_3}{M_J} \frac{n_2}{\nu_2} \frac{a_2}{a_3} C_2 \exp(iV_2) \quad (12)$$

When this solution is substituted back into the differential equation for  $n_1$ ,  $n_2$  and  $n_3$ , we obtain the interaction involving the resonance argument  $\phi = V_1 - V_2$ .

$$\frac{d^2\phi}{dt^2} + An_2^2 \sin \phi + cn_1(1 - 45.0De_1^2) = 0 \quad (13)$$

$$\frac{d\nu_1}{dt} + 0.68An_2^2 \sin \phi + cn_1(1 - 34.6De_1^2) = 0 \quad (14)$$

The coefficient  $An_2^2 \approx -0.03858 (1 + 0.19 \cos \phi) (^\circ \text{ d}^{-1})^2$  if we include contributions from higher order effects (J. Lieske, personal communication).

The secular acceleration of  $\phi$  and  $V_1$  vanish when Io's forced eccentricity  $\approx 1/(13D)^{1/2}$ . As this eccentricity is 1.5 times larger than that necessary to maintain the 2:1 Io-Europa lock, this implies that the system passes through the capture phase (that is, when  $\dot{\phi}$  vanishes and reverses sign) with the smaller eccentricity. After the three body lock is established, Io's eccentricity is pumped up until the quasi-stationary state is achieved.

**Fig. 2** Relative location of Io-Europa at equal time intervals before (b) and after (a) conjunction. Because of the tidal offset  $\delta$  in Io's pericentre,  $\Delta_b > \Delta_a$  and the average tangential torque repels Io from Europa.

The torque acting to repel Ganymede results from an offset of the resonant argument  $\phi$  from  $180^\circ$ . Actually, the transfer of momentum from Europa to Ganymede involves the same kind of mechanism outlined for the 2:1 case, except that in this case the offset in the forced motion of Europa's pericentre by Ganymede is coupled directly to the offset driving the Io-Europa pair. The next problem to resolve is the capture mechanism.

One mechanism for changing the energy and the libration amplitude of a pendulum-like equation is through the addition of a  $\dot{\phi}$  term. The dominant  $\dot{\phi}$  term in this case comes from the resonance-induced variation of Io's forced eccentricity which is inversely proportional to  $\nu_1 = n_1 - 2n_2$ . From analysis of the equations of motion (4-7, 13, 14) we find that near the three-body resonance the variations are  $\delta n_1 \approx 0.125\dot{\phi}$ ,  $\delta n_2 = -0.276\dot{\phi}$  and  $\delta n_3 = 0.023\dot{\phi}$ . The additional term to be added to the left hand side of equation (13) is therefore

$$+60.8cDe_1^2 n_1 \nu_1^{-1} \dot{\phi} \quad (15)$$

The coefficient of  $\dot{\phi}$  is positive, implying that the librational energy is reduced through this term. The resulting differential equation describing the motion and tidal evolution of the three-body resonance happens to be nearly identical to that of spin-orbit resonance<sup>8,9</sup>. An estimate of the probability that capture into resonance occurs can be obtained from comparing the change in the kinetic energy during the cycle that  $\dot{\phi}$  reverses sign to the maximum change per cycle. The resulting capture probability  $P_c$  is given by

$$P_c = \frac{2}{1 + \pi/4 [1 - 45De_1^2 / 60.8De_1^2 \nu_1^{-1} A^{1/2} n_2]} \quad (16)$$

Evaluating this expression with the appropriate values of  $e_1$ ,  $\nu_1$  and  $A$  at capture we find  $P_c \approx 0.90$ . Capture into the three-body resonance is almost certain.

The damping of the libration amplitude  $\phi_m$  is approximately described by<sup>9</sup>

$$2 \sin \frac{1}{2} \phi_m \approx \left( \frac{16}{\pi} \right)^{1/2} \left( \frac{A(0)}{A(t)} \right)^{1/4} \exp \left( -\frac{1}{2} \int \sigma(t) dt \right) \quad (17)$$

where  $\sigma = 60.8cDe_1^2 n_1 \nu_1^{-1}$ . Because forced  $e$  increases from  $1/(35D)^{1/2}$  to  $1/(13D)^{1/2}$  the coefficient  $\sigma$  varies from  $\sim 250c$  up to  $1,100c$ . The secular decrease of  $\nu_1$  can be obtained from averaging equations (13) and (14). The result is

$$\frac{d\nu_1}{dt} = -0.32cn_1(1 - 12.5De_1^2) \quad (18)$$

Given that  $\phi_m = 1.1 \times 10^{-3}$  ( $0.066^\circ$ ), we find that the time since capture  $\Delta t \approx 0.024c^{-1} = 1,200 Q_1$  yr. Furthermore, the relative change in Io's semi-major axis is only 0.7%. On the other hand, the present forced eccentricity  $\approx 1/(13.8D)^{1/2}$  is very near the limiting value of  $1/(12.5D)^{1/2}$ . From this we can deduce that  $D \approx 4,300$ . Limits on  $Q_1$  can be obtained from a comparison of the rate of tidal heating to that expected from radiogenic sources and an estimate of the total heat input during the lifetime of the three-body resonance.

From equating the rate of change in Io's orbital energy by the satellite tide to the tidal heating rate  $dE_1/dt$ , we obtain

$$\frac{dE_1}{dt} = \frac{1}{3} M_1 n_1 a_1^2 \frac{dn_1}{dt} \left( \frac{\text{Io}}{\text{tide}} \right) = \frac{7}{3} M_1 n_1^2 a_1^2 c D e_1^2 \quad (19)$$

The resulting estimate for the rate of heating is  $3.0 \times 10^{25} Q_1^{-1} \text{ erg s}^{-1}$ . This is to be compared with the radiogenic value of  $5 \times 10^{18} \text{ erg s}^{-1}$  for a body of Earth-like composition. The apparent fact that Io is much more active than the Earth suggests that  $Q_1 \ll 2 \times 10^6$ , if we assume that for a given heat input that surface activity scales with radius.

The total heat deposited in Io per gramme of material during the three-body resonance lifetime is only  $0.9 \times 10^{10} \text{ erg g}^{-1}$  or  $260 \text{ cal g}^{-1}$ . If no heat is lost, the mean temperature rise is  $\sim 900 \text{ K}$ , which is enough to partially melt Io.

A lower bound of  $Q_1$  of  $\sim 2 \times 10^5$  and an upper bound of the heat input in Io of  $\sim 10^4 \text{ cal g}^{-1}$  can be obtained from the condition that Io has significantly tidally evolved and that the 2:1 resonance lifetime is the age of the Solar System. The tidal heating of Europa is at most  $\sim 100 \text{ cal g}^{-1}$  because of its very small eccentricity ( $\approx 0.0014$ ) during the 2:1 resonance lifetime.

Voyager 1 images of Europa (fly-by distance  $\sim 750,000 \text{ km}$ ) revealed long linear features that may be due to tidally induced fracturing. The relative age of these features may be deduced from the much more detailed Voyager 2 images of Europa (fly-by distance  $\sim 190,000 \text{ km}$ ; resolution  $\sim 5 \text{ km}$ ). If indeed these features are of tidal origin, then they should have been produced in the past  $10^3 Q_1$  yr during which Europa's forced  $e$  has increased from 0.0014 to 0.0101.

It should be emphasised that all of the above conclusions are predicated on Lieske's solution for the libration amplitude and, of course, the story changes if this measurement happens to be spurious. The major change is that the three-body resonance may be very old. The lower bound on  $Q_1$  is then reduced to  $\sim 8 \times 10^4$  while the heat deposited in Europa could be as high as  $10^4 \text{ cal g}^{-1}$  because of its much larger forced  $e$  once the three-body resonance is established.

In the expansion of the Sun-satellite gravitational interaction, a forcing term exists with argument  $2\lambda_1 - \Omega_3 - \psi$  and a period of 2,076 d which is very near the libration period of  $2,074 \pm 10 \text{ d}$  (J. Lieske, personal communication).  $\Omega_3$  refers to the node of Ganymede's orbit and  $\psi$  to the node of Jupiter's equator to the jovian orbit. The amplitude of the forcing term is very sensitive to the difference in these periods. The determination of whether this observed libration amplitude is in reality due to this forced term rests primarily in improving the masses of the galilean satellites.

On the other hand, a more sophisticated tidal analysis which includes the third harmonic tides on Jupiter, europian tides and higher order contributions to the coefficient of the  $\dot{\phi}$  term are not expected to change the primary conclusion that the three body was established recently nor alter the above numerical estimates by more than  $\sim 20\%$ .

There are other observables which can be used to estimate the rate of dissipation in Io. Since Io is about the same distance from Jupiter as the Moon from the Earth, the maximum recession of Io should be no more than that found for the Moon ( $\sim 3 \text{ cm yr}^{-1}$ ) and is completely negligible. On the other hand, the variation in Io's longitude times its semi-major axis is quadratic in time. For a rate of  $1.5 \text{ cm yr}^{-1}$ , the magnitude is  $150 \text{ km}$  ( $\Delta t^2$  in cent.) and might be detectable using  $\sim 100$  yr old eclipse data.

Other possibilities are polar wander (thought to be driven by mantle convection on Earth) and a slightly faster than synchronous rotation. This latter possibility occurs if the non-hydrostatic component of the moment of inertia difference  $(B - A)/C$  is small compared with the average, periodic tidal component. The minimum time scale for either effect is set by the relaxation time  $\sim \eta h / \rho g R^2$  of the zero frequency tidal bulge. If the viscosity  $\eta \approx 10^{22}$  St (like the Earth's asthenosphere) and the crustal thickness  $h \sim 100$  km, this time scale is  $\sim 100$  yr. Thus these effects are unlikely to be observable from image analysis of the Voyager 1 and 2 fly-bys which are separated by only 154 d.

### Other implications

Some variants of this sequence of events can be dismissed because of their low probability. It is unlikely that Io first encounters the three-body resonance well before the 2:1 near commensurabilities are achieved, because the capture probability, which scales like  $\nu^{-7/2}$ , would be small. The possibility that Europa might have tidally evolved into a quasi-stationary 2:1 commensurability with Ganymede first limits the heat input in Io to  $\sim 200 \text{ cal g}^{-1}$ . This amount of heat is probably insufficient to drive the observed surface activity.

Another variation is that Io's forced eccentricity, when Io encountered either the 2:1 or three-body resonance, may have been pumped up significantly larger than its present value. This would be expected if Io were initially more rigid than at present because of the absence of a large fluid core. The nearly elastic periodic tides would rapidly build up until the elastic limit is reached after which massive satellite-wide fracturing occurs. The catastrophic increase in tidal dissipation and perhaps tide height could provide the trigger for core formation.

Among the other satellite resonance locks, only the saturnian pair Enceladus-Dione has an *e*-type lock where the free eccentricity of one member is exceptionally small. The forced eccentricity of Enceladus is 0.0044 while the free eccentricity is  $\sim 1 \times 10^{-4}$ . Enceladus is apparently a small icy satellite ( $M = 1.5 \times 10^{-7} M_S$ ,  $R \approx 270$  km and  $\rho \sim 1.0 \text{ g cm}^{-3}$ ). The parameter  $D \sim 60$  if we assume  $\mu \approx \mu_{\text{ice}} \sim 9 \times 10^{10}$  and  $Q_s/Q_{\text{En}} = 10^3$ . Thus it is unlikely that this pair has reached a steady state configuration. It is possible that originally  $e_{\text{En}}$  was pumped up to some critical eccentricity which caused catastrophic fracturing. The effective rigidity may have been sufficiently reduced, such that this pair too has achieved a quasi-stationary orbital configuration. The Voyager 2 fly-by of Enceladus may reveal another curious satellite whose past and present state is controlled by tidal friction.

### Conclusions

We conclude that tidal dissipation in Io is a plausible energy source for the volcanic activity and is the controlling mechanism which leads to the establishment and the present state of the several resonance locks. The most plausible sequence of events is in four stages. (1) All three satellites are in orbits far from either the 2:1 commensurabilities or the three body lock. The tide raised on Io quickly damps down the free eccentricity on a time scale  $\leq 10^5 Q_1$  yr. Only modest tidal heating in Io occurs. (2) The dissipative tide raised on Jupiter by Io is dominant and causes Io's orbit to spiral outwards. No significant tidal heating occurs. Io approaches the 2:1 commensurability with Europa in stage (3). Io's forced eccentricity rapidly increases to the critical value  $\sim 1/(35D)^{1/2} \sim 0.0026$ . Thereafter the resonant interaction causes Europa's orbit to expand at exactly half that of Io's orbit. Tidal heating probably leads to the formation of a fluid core. Finally (4) Europa approaches the 2:1 commensurability with Ganymede but instead of dissipation in Europa repelling Ganymede we find that Io must work even harder using the three-body resonance to transfer angular momentum from Europa to Ganymede's orbit. We again rapidly reach a steady state as  $e_{\text{Io}}$  approaches  $1/(13D)^{1/2}$ .

Based on the observed three-body resonance amplitude of  $0.066^\circ$ , we have concluded that the three-body resonance was established  $1,200 Q_1$  yr ago. About  $220 \text{ cal g}^{-1}$  could have been deposited by tidal heating during this interval and is just sufficient to produce a large fluid core in Io. The 2:1 near commensurability of Io may be considerably older than the three body lock. Upper and lower limits of  $Q_1$  are  $2 \times 10^6$  and  $2 \times 10^5$ . Analysis of Voyager data should provide an estimate of the energy necessary to drive Io's volcanic activity and provide a firm estimate of the jovian  $Q_1$ .

## A twin-jet model for radio trails

Mitchell C. Begelman & Martin J. Rees

Institute of Astronomy, Madingley Road, Cambridge, UK

Roger D. Blandford

California Institute of Technology, Pasadena, California 91125

*Radio trails are interpreted in terms of the twin-jet theory of double radio sources. A simple dynamical model of a narrow jet bending under the ram pressure of the intra-cluster medium is calculated and applied to some observations of the source associated with NGC1265. Observed radio emission must come from the interior of the jet, which is surprisingly stable to disruptive instabilities.*

RADIO TRAILS (head-tail sources, twin-tail sources) are a distinctive morphological class of weak extragalactic radio sources<sup>1,2</sup>. The most natural interpretation of their radio shape is that the associated active elliptical galaxy, which would otherwise have produced a normal double source, belongs to a cluster and is moving at  $\geq 1,000 \text{ km s}^{-1}$  through an intracluster gas<sup>1</sup>. The radio-emitting regions are then swept backwards by ram pressure. The wide-angle trails (bent doubles<sup>2</sup>) such as 3C465<sup>3,4</sup> are an intermediate category where the motion of the galaxy

causes distortion to a lesser degree. The two best studied radio trails are 3C83.1B<sup>5-8</sup>, associated with the galaxy NGC1265 in the Perseus cluster, and 3C129<sup>5,6</sup>.

In many weak radio sources, there is now good morphological evidence<sup>2,9,10</sup> for continuous energy supply, via collimated jets or beams emanating from the nucleus of the associated galaxy or quasar<sup>11-13</sup>. Recently, Owen *et al.*<sup>8</sup> have produced a high resolution map of NGC1265 in which narrow, quasi-continuous streams can be seen emerging from the nucleus of a galaxy associated with a radio trail. These streams have a transverse angular scale  $\leq 2''$  and appear to be bent back into a curved arc until, at a distance  $\sim 30$  kpc from the nucleus (assuming a distance to the cluster of 100 Mpc), the jets disappear in high surface-brightness features and presumably merge into the trail. The radio emission from the beam at  $\leq 5$  GHz is  $\sim 10^{40}$  erg s<sup>-1</sup>, only a few per cent of the radio luminosity of the tail.

As argued by Owen *et al.*<sup>8</sup> these observations pose difficulties for the 'discrete blob' model of radio sources<sup>14-16</sup> in which independent gas clouds plough through previously undisturbed intergalactic medium. The distinctive feature of a jet interpretation is that each element of gas moves along a pre-established track (whose curvature is determined by the mean momentum discharge averaged over the recent history of the source) rather than on a trajectory depending on its individual cross-section and inertia. In NGC1265, the fact that there is a bright unresolved nuclear source indicates continuing activity and outflow from the galactic centre.

Here we give a simple discussion of the dynamics and equilibrium of a curved jet, assuming that the jet carries a steady flux of energy and momentum, and ignoring all complexities stemming from instabilities, entrainment, and so on. Then we make some quantitative estimates for NGC1265, and discuss the relationship between the curved jet and the extended tail. Further implications and various difficulties are also discussed.

## Dynamics of a curved jet

Consider a narrow, collimated, supersonic jet emerging from the central region. It must come into dynamical equilibrium with the pressure of the cluster gas sweeping past the jet. The flow pattern that we envisage is shown in Fig. 1. The intracluster medium (ICM) of electron density  $n_c$ , temperature  $T_c$ , flows towards the jet with the galaxy's velocity with respect to the centre of the cluster,  $V_g$ . We ignore gas motion in the ICM and assume that there is no significant mixing between the jet and the ICM, justifying this assumption *a posteriori*. If the galaxy moves supersonically, there will be a cylindrical stand-off bow shock; the stagnation pressure at the origin, where the jet is perpendicular to  $V_g$ , will exceed the ambient ICM pressure by  $p_0 = 2.9 M_g^2 n_c k T_g$  where  $M_g$  is the Mach number associated with the galaxy's motion through the ICM<sup>17</sup>. (This formula is also approximately valid for subsonic motion). The jet will be accelerated transversely within this transition region and the density profile will adjust to establish a pressure gradient across the jet, and to come into pressure equilibrium with the ICM either by expanding through a series of rarefaction waves or through being heated by a combination of weak shocks and compression waves. Downstream from the jet, the flow will come into rough pressure equilibrium with the ambient ICM and so the pressure difference across the jet will be roughly the same as  $p_0$ .

The rate of bending of the jet is governed by the jet density profile. In order to calculate a simple model, we treat the jet velocity  $V_j$  as constant, and the jet fluid as having a temperature  $T_j$  which depends on distance along the jet. We approximate the complex gas flow by relating the pressure at the jet surface to the stagnation pressure by the factor  $\cos^2 \phi$ , where  $\phi$  is the angle between the surface normal and the surface normal at the stagnation point<sup>18</sup> (see Fig. 1). This relates the pressure to the momentum flux incident on the surface in the shocked ICM. In cross-section, the jet profile then has the form  $y = 2h \cos^{-1} [\exp(-x/2h)]$  where the scale height is  $h = 2kT_j/m_p g$ ,

**Fig. 1** Schematic diagram of the bending of a jet by a transverse supersonic flow. Axes  $X, Y$  describe the equilibrium shape of the jet in a frame moving with the galaxy. Axes  $x, y$  describe the profile of the jet in cross-section. The pressure difference across the jet is comparable with the ram pressure of the intracluster medium. In the jet, this is opposed by the centrifugal force associated with the curved trajectory. After bending through a large angle, the jets disrupt and share their mass, momentum and energy fluxes with the shocked intracluster medium. Dissipation of relative kinetic energy creates a mixing region of transverse size  $\sim w$ . The mixture of thermal gas, relativistic particles and magnetic field flows downstream away from the galaxy to form the tail.

where  $g$  is the effective acceleration felt by the material in the jet as it follows its curved path.

We make a similar assumption about the variation of the pressure  $p$  along the jet axis. In a frame such that  $X$  and  $Y$  are the coordinates of the jet relative to the point where the velocity is perpendicular to the galaxy's velocity, the jet curvature is  $Y''(1 + Y'^2)^{-3/2}$ . For a given effective specific heat ratio  $\gamma$  in the jet we can calculate the trajectory from

$$g = V_j^2 Y''(1 + Y'^2)^{-3/2} = \frac{p_0}{n_{j0} m_p h_0} (1 + Y'^2)^{(1/2)\gamma - 1} \quad (1)$$

The stagnation pressure, jet electron density and scale height are  $p_0$ ,  $n_{j0}$  and  $h_0$  respectively. The scale height varies along the jet as  $h = (1 + Y'^2)^{1/2\gamma} h_0$ . From equation (1) we see that the jet Mach number  $M_j$  is related to the radius of curvature  $R_0$  at the stagnation point by<sup>19</sup>

$$M_j = (R_0 / \gamma h_0)^{1/2} \quad (2)$$

Note that if  $n_c$  and  $V_g$  are known, and  $h$  can be estimated from the radio contours, then the momentum flowing along the jet,  $\pi n h_0 R_0 p_0$ , can be inferred from the observations (apart from projection effects). The energy flowing along the jet is larger by the unknown factor  $V_j/2$ .

## Application to NGC1265 (3C83.1B)

The galaxy NGC1265 has a radial velocity  $\sim 2,300$  km s<sup>-1</sup> relative to the mean velocity of the Perseus cluster. Then

$$V_g \sim 2,300 \text{ sec } i \text{ km s}^{-1}; \\ M_g \sim 2.1 (T/5 \times 10^7 \text{ K})^{1/2} \text{ sec } i \quad (3)$$

where  $i$  is the angle between the galaxy's velocity (relative to the cluster centre) and our line of sight and  $T$  is the temperature of the ICM. If NGC1265 is bound to the Perseus cluster, then  $\cos i \geq 0.6$ .  $n_c$  is probably  $\sim 3 \times 10^{-4}$  cm<sup>-3</sup>; the X-ray data suggest  $T_c \sim 5 \times 10^7$  K, implying that  $M_g$  lies between 2 and 4, and vindicating our assumption of supersonic flow.

The internal pressure within the beam at the stagnation point is

$$p_0 \approx 3 \times 10^{-11} (n_c / 3 \times 10^{-4} \text{ cm}^{-3}) \text{ sec}^2 i \text{ dyn cm}^{-2} \quad (4)$$

An important check of the self-consistency of this model for NGC1265 is then to ask whether this value of  $p_0$  permits a high enough volume emissivity to account for the observed radio emission. This emission is non-uniform along the jet, the mean value being  $\sim 5 \times 10^{-12}$  dyn cm $^{-2}$ . This value is calculated on the assumption that the spectrum extends, with spectral index 0.8, up to 10 GHz (see ref. 8), but making no allowance for relativistic protons. In the individual 'hot spots' the pressure is higher; the precise value depends on the detailed geometry, but an estimate would be  $\geq 4 \times 10^{-11}$  dyn cm $^{-2}$ . The corresponding equipartition field is in the range  $(1-4) \times 10^{-5}$  G. Comparing these two estimates of the pressure we conclude that the magnetic and relativistic electron components of the jet fluid must be in approximate equipartition, and the thermal particles (though they may greatly outnumber the relativistic particles) cannot dominate the pressure. Furthermore, the radio emission cannot come from a region (for example, a thin surface layer or ribbon) involving some small fraction of the cross-section assumed on the basis of cylindrical symmetry.

The synchrotron lifetime for an electron emitting at 5 GHz in the equipartition field is  $\sim 5 \times 10^6$  yr which is of the order of 10 times the time for the ICM medium to flow past the jet and probably shorter than the flow time along the jet. This argues in favour of emission from the jet itself rather than from a sheath of shocked ICM and indicates the need to reaccelerate relativistic electrons *in situ*. The most surprising implication of this model, however, is the small fraction of the jet kinetic energy that is dissipated along its length. The precise relationship between the radio emissivity and the jet geometry obviously depends on very specific details of the model. In almost every hypothesis, however, the transverse extent of the radio contours would correspond at least to a scale  $h$ . The narrowness of the observed radio jet then implies that  $(h/R) \leq 0.05$ , so that  $\leq M_j^{-2} \approx 0.05$  of its kinetic energy can have gone into internal energy. Unless, for example the jet is a powerful millimetre source, it is impossible that a large fraction of the jet kinetic energy be radiated away, because the total observed jet luminosity is  $\leq 0.02$  of the radio power of the tail. These considerations in turn imply that the fraction of the ICM material impacting on the beam which can be entrained must be  $\leq M_j^{-2} (V_g/V_j)$ .

There is therefore observational support for the simple dynamical model of the jet outlines above. We have integrated equation (1) for a specific heat ratio of 5/3 (using  $\gamma = 4/3$  makes little difference). The resulting flow must be projected onto the sky. We have used  $\cos i = 0.8$  and varied the angle  $j$  between the jet axis and the line of sight to obtain a rough fit to the shape of the observed radio contours. This is shown in Fig. 2. We find that  $j \sim 60^\circ$ . If the jet angular width near the galaxy is  $\delta$ , then  $M_0 \sim 6(\delta/l'')^{-1/2}$ , and the existence of unresolved features  $\leq 0.5''$  in size suggests that  $M_0 \geq 8$ . However, if we take the width of a smooth trajectory enveloping the faintest contour, then we obtain  $M_0 \sim 4$ . The angle between the jet axis and the galaxy's velocity is  $\sim 80^\circ$ , and it is the closeness of this to  $90^\circ$  that is perhaps responsible for the unusually symmetric appearance of NGC1265.

Polarisation observations can in principle provide information on the density and hence  $V_j$ . The observations of Owen *et al.*<sup>8</sup> do not provide polarisation data but if the reported 30% polarisation<sup>7</sup> is due to the narrow jet, it implies highly ordered internal field structure, probably aligned along the jet by shearing motions. If the thermal plasma is uniformly distributed throughout the jet and not contained in dense clouds, then lack of depolarisation implies that  $n_i \leq 0.06$ . This is not a very significant limit. However, if the same level of polarisation in the narrow jet persisted down to lower frequencies it would set a more stringent limit on  $n_i$ , and thereby set a lower limit on  $V_j$ . If, for instance, the jet remained highly polarised down to 400 MHz,  $n_i$  would have to be so low that the required momentum flux could be supplied only if  $V_j$  exceeded  $\sim 10^6$  km s $^{-1}$  (a value that seems likely on other grounds).

The total luminosity of the tail is  $\sim 6 \times 10^{41}$  erg s $^{-1}$ . There is unlikely to be sufficient kinetic energy flux associated with the

Fig. 2 VLA map of 3C83.1B at 4,886 MHz reproduced from Owen *et al.*<sup>8</sup>; only contours in the vicinity of the jet have been drawn. The shaded ellipse represents the half power contour of the clean beam, corresponding to a resolution of  $1.5'' \times 1.0''$ . Superimposed on this map is a trajectory obtained from integrating equation (1).

ICM to supply this. If this energy were all supplied by the jet then even assuming 100% efficiency we would infer, from our estimate of the momentum flux, a lower bound on  $V_j$  of 4,000  $(\delta/l'')^{-1} (n_c/3 \times 10^{-4} \text{ cm}^{-3})^{-1/2}$  km s $^{-1}$ . The jets appear (at least on one side) to break up after bending through  $\sim 75^\circ$ . The jet material may then share its momentum with the shocked ICM downstream (M.C. Begelman, in preparation), the energy thereby dissipated going into the production of a sheared magnetic field and into particle acceleration. The magnetic field strength within the tail region (assuming equipartition between the thermal gas, relativistic electron and magnetic energy, and pressure balance with the ambient ICM pressure) is  $\sim 10^{-5} (n_c/3 \times 10^{-4} \text{ cm}^{-3})^{1/2} (T_c/5 \times 10^7 \text{ K})^{1/2}$  G; lower by a factor  $\sim M_*$  than the field strength in the jet and slightly greater than the equipartition value inferred from observations. The tail has a width  $W \sim 40$  kpc and is highly polarised with a rotation measure  $\sim 30$  rad m $^{-2}$ . If the magnetic field is aligned parallel to the tail, as is expected if it is amplified by shear, then we can estimate the tail electron density to be  $n_t \sim 10^{-4} \text{ cm}^{-3}$ . For comparison, the mean electron density in the jet plasma is only  $\sim 10^{-6} (\delta/l'')^{-1} (V_j/10,000 \text{ km s}^{-1})^{-1} \text{ cm}^{-3}$  and so there must be some mixing with the ICM. In any case,  $n_t$  is smaller than  $n_c$ ; hence this model supports the idea that buoyancy is important in shaping the outermost parts of the tail<sup>16,20</sup>.

## General implications

Our basic starting point has been to assume that the tail of NGC1265 is energised by a 'twin-jet' emerging from the nucleus. This assumption is supported by the smooth arc-shaped curvature manifested in the high-resolution radio maps, the existence of an active radio nucleus in NGC1265, and by analogies with normal double sources. This interpretation requires that the jets be surprisingly stable and resistant to Kelvin-Helmholtz instabilities: the intergalactic wind flows across the beam with very little mixing or entrainment. The jets are able to maintain a Mach number  $\geq 4$  whilst being curved through an angle  $\sim 70^\circ$ . We would conjecture that the real flow pattern has no sharp velocity discontinuities: small-scale instabilities would certainly be inhibited if the shear layer actually had a thickness comparable with  $h$ .

We note also that the density profile across the jet is unlikely to follow the simple exponential law that we have assumed in our explicit model. Moreover, the flow pattern of the intergalactic medium through the galaxy is presumably much more complex than the uniform wind we have considered; even if there is not a large 'dead zone' of gas trapped in the galaxy's potential well, the flow pattern is likely to be modified by the entrainment of gas

resulting from stellar mass-loss in the galaxy. Our estimates of the energy flux and momentum flux along the jets are, fortunately, insensitive to these details. From the power requirements in the tail, we can guess that  $V_j \approx 10^4 \text{ km s}^{-1}$ . This corresponds to a flow time along the jet of  $2 \times 10^6 \text{ yr}$ , a power  $\sim 2 \times 10^{42} (n_c/3 \times 10^{-4} \text{ cm}^{-3})(\delta/1'')(V_j/10^4 \text{ km s}^{-1}) \text{ erg s}^{-1}$  and a mass discharge  $\sim 0.05 (n_c/3 \times 10^{-4} \text{ cm}^{-3})(\delta/1'')(V_j/10^4 \text{ km s}^{-1})^{-1} M_\odot \text{ yr}^{-1}$ . The energy and mass fluxes required of the nucleus are very small compared with those of the most powerful doubles.

The irregularities in the radio contours delineating the jet path imply either that its properties are unsteady or that there are instabilities along its path. The latter would not be unexpected—what seems astonishing is that the jet is stable enough to persist at all when exposed to a strong transverse force. Variations in the central energy supply—involving changes in  $V_j$  or in the internal properties of the ejecta—will also lead to nonuniformities along the track of the jet. If the jet were ever to switch off, the channel which it had made would persist for a time  $\sim 3h/V_j \sim 10^6 \text{ yr}$ . Variations on timescales less than this would lead merely to inhomogeneity but if the nuclear activity revived after a dormant phase longer than this, the jet would need to be re-excavated; a bow shock would advance out at a speed  $\sim M_j V_g$  as in the standard model for a double radio source component.

We have shown how the high resolution observations of NGC1265 may be interpreted in the context of a jet model and have constructed a simple equilibrium gas flow to describe the overall morphology. It remains to be shown that this flow is not subject to serious disruptive instabilities until the jet has bent through an angle  $\geq 70^\circ$ . The best hope for investigating

empirically the importance of these instabilities is perhaps with laboratory wind-tunnel experiments.

Finally, we note that, although other radio trails may not show such symmetric arc-shaped central structure when studied with  $\sim 1''$  resolution,<sup>21</sup> the same qualitative picture can apply. NGC1265 must be unusual in that not only do its velocity and beam axis both have substantial components transverse to the line of sight, but, furthermore, the beams happen to be directed almost perpendicular to the galaxy's motion through the IGM.

We thank J. Burns and F. Owen for a preprint about NGC1265. R.D.B. was supported in part under NSG grant AST78 05484, and acknowledges hospitality at the Institute of Astronomy.

## Sequence, structure and activity of phosphoglycerate kinase: a possible hinge-bending enzyme

R. D. Banks, C. C. F. Blake, P. R. Evans\*, R. Haser† & D. W. Rice

*The fitting of sequenced peptides to a high-resolution X-ray map of phosphoglycerate kinase has yielded the complete sequence and structure of the horse muscle enzyme. Metal ADP and ATP substrates are bound to one of the two widely separated domains in an environment that seems unsuitable for phosphoglycerate binding. The most plausible binding site for the phosphoglycerate substrate is on the other domain about 10 Å from the ATP, which implies the possibility of a large scale hinge-bending of the domains to bring the two substrates together in a water-free environment for catalysis.*

PHOSPHOGLYCERATE KINASE (EC 2.7.2.3; PGK), catalyses the high-energy phosphoryl transfer reaction:

The enzyme is required for ATP generation in the glycolytic

pathways of aerobes and anaerobes, and for carbon fixation in plants. PGKs isolated from a wide variety of sources are monomeric with molecular weights around 45,000, with comparable amino acid compositions and similar catalytic properties. This has led to the proposal<sup>1</sup> that the enzyme has a highly conserved molecular and active site structure.

Preliminary X-ray studies of the horse muscle<sup>2,3</sup> and yeast enzymes<sup>4,5</sup> have shown that they are structurally homologous. The most remarkable feature of the PGK molecule is that its single polypeptide chain is organised into two widely separated domains of almost equal size. The results we report here suggest that this feature of the tertiary structure is probably associated with a large-scale 'hinge-bending' conformational change in the enzyme that is broadly similar to that previously reported for hexokinase<sup>22</sup>.

\* Present address: MRC Laboratory of Molecular Biology, Hills Road, Cambridge, UK.

† Present address: Centre de Recherche sur les Mécanismes de Croissance Cristalline, CNRS Faculté des Sciences et Techniques de Saint-Jerome, 13397 Marseilles Cedex 4, France.

## Experimental methods

Initially, a three-dimensional electron density map of horse PGK was obtained by conventional isomorphous replacement, using two derivatives, ethylmercuric phosphate and ethylmercuric chloride, each of which react with up to six of the enzyme's seven sulphhydryl groups. The X-ray intensities of the native enzyme and the two derivatives were collected on a five-counter, five-circle diffractometer<sup>7</sup> to 2.5 Å resolution. The data were corrected for Lorenz polarisation and radiation damage, and for absorption using the Huber-Kopfmann technique<sup>8</sup>. The phases of the 13,000 structure factors were estimated using the isomorphous and anomalous contributions of the heavy atoms. In parallel with the incorporation of the side-chain information from the sequenced peptides (see below), the protein structure was subjected to crystallographic refinement using the Hendrickson-Konnert constrained least squares program<sup>9</sup>, and the resultant calculated phases combined with the isomorphous phases using Hendrickson's method<sup>10</sup> to produce improved electron density maps. This procedure was carried out in three stages using: (1) main-chain atoms only (including  $\beta$ -carbons); (2) main chain + 200 available side chains; (3) main chain + 400 available side chains. As shown in Table 1 at each stage the conventional *R* factor for the refinement decreased, the figure-of-merit of the combined phases increased, and the new electron density maps improved markedly in interpretability.

The sequence analysis was carried out using both automated and manual Edman degradation of cyanogen bromide peptides and fragments derived from them by digestion with proteolytic enzymes. Treatment of horse muscle PGK with cyanogen bromide produced the 14 peptides consistent with the presence of 13 methionine residues in the molecule. The cyanogen bromide peptides were separated by gel filtration, ion-exchange chromatography, and where necessary, paper electrophoresis. The sequences of the individual peptides were obtained by a combination of automated Edman degradation using a Beckman 890C Sequenator, and the dansyl-Edman technique<sup>11</sup>. As with the enzymes from yeast, rabbit muscle<sup>12</sup> and human erythrocytes<sup>13</sup>, horse muscle PGK was found to have a blocked N-terminus. Thermolytic digestion of the N-terminal cyanogen bromide peptide revealed an *N*-substituted serine derivative, which was shown to be *N*-acetylserine by mass spectrometry.

Alignment of the sequenced cyanogen bromide fragments was carried out on the X-ray map. The six peptides containing more than 30 residues were fitted first. Their possible location on the molecule was determined using the following criteria: (1) each peptide began and ended at plausible methionine residues in the map; (2) any cysteine residues present in the sequence were located near one of the six known sites of mercurial binding; (3) Phe, Tyr and Trp residues in the sequence coincided with large side-chain densities; and (4) each of the 12 internal  $\beta$ -strands in the map corresponded to consecutive sequences of

four to six hydrophobic residues. The remaining eight peptides, which had 20 or fewer residues, often did not fulfil a sufficient number of criteria for an independent fit to be made with much confidence. Instead, when the sequence or lengths of all of them were available, they were fitted into the gaps between the longer peptides. Each fit was considered confirmed only when, in addition to all other criteria, it was found that internally positioned side-chains corresponded almost without exception to hydrophobic residues, and there was a good match of size and shape of the sequenced residues to their electron densities.

The 14 peptides were accommodated on the X-ray map in an end-to-end fashion, covering the complete polypeptide chain visible in the map. This fit is shown in Fig. 1, with the methionine residues marked to indicate the linkage of the sequenced peptides. The total of 416 residues in the polypeptide chain of horse muscle PGK corresponds to a molecular weight of 44,519, in good agreement with independent determinations<sup>1</sup>; and the total numbers of each type of amino acid residue are consistent with the overall amino acid composition<sup>14</sup>. Preliminary comparison of this sequence with peptide sequences from yeast PGK suggests a considerable degree of homology between the enzymes (L. A. Fothergill, personal communication).

## Molecular structure

Figure 2 shows a drawing in the conventional arrow and cylinder form of the tertiary structure of phosphoglycerate kinase. The division of the molecule into two discrete, separated globular domains can be seen clearly. It is now evident that the domains correspond to the N-terminal and C-terminal halves of the polypeptide chain, with the sole exception that the final 12 residues of the chain, forming helix 15, are packed in the N-terminal domain. There are therefore two links between the domains; the major one represented by residues 186–189 that form the junction between  $\beta$ -strand F and helix 7; and the minor one around residues 404–406 that connects helices 14 and 15. It is interesting to note that no element of regular secondary structure crosses the domain interface: strand F is clearly part of the N-domain, whereas helix 7 is associated with the C-domain; helices 15 and 14, respectively, are similarly disposed.

The N- and C-domains are almost precisely the same size and each is composed of a central  $\beta$ -sheet of six parallel strands surrounded by helices. In topological terms the order of the  $\beta$ -strands in the C-domain (CBADEF) is the same as that in the NAD-binding domain of the dehydrogenases<sup>15</sup>; whereas the order in the N-domain (CDBAEF) differs only in the location of strand D. There are, however, no significant similarities in the sequences of the two domains and their detailed structures are different. As in other glycolytic enzymes<sup>6</sup> there is a marked tendency for the secondary structural elements to be organised as repeating ( $\beta$ - $\alpha$ ) units<sup>16</sup>: in PGK the ( $\beta$ - $\alpha$ ) motif is repeated 12 times.

In total, the PGK molecule has 15 helices, 12 internal  $\beta$ -strands, and at least five surface  $\beta$ -strands. On the basis of the number and extent of the secondary structural elements shown in Figs 1 and 2, the PGK molecule has a minimum of 104 residues located in  $\beta$ -structures, and 174 in helices: these numbers represent 25% and 42% respectively of the residues in the molecule.

## Substrate binding

Horse PGK crystals grown in ammonium sulphate and equilibrated in potassium tartrate bind AMP and the complexes of ADP and ATP with  $Mg^{2+}$  or  $Mn^{2+}$ , at a single site on the C-terminal domain. The difference maps of MgATP at 3 Å resolution, and of MnATP at 2.5 Å resolution are sufficiently detailed for the conformation<sup>17</sup> of the bound nucleotide to be determined. The base is in the *anti* conformation with respect to the sugar, ( $\chi \sim 80^\circ$ ); the sugar pucker is C3' *endo*; and the conformation about the exocyclic C4'–C5' bond is *gauche* (–) (or *trans-gauche*). The triphosphate chain of ATP is in a somewhat coiled conformation and directed away from the adenine

**Table 1** Statistics of the X-ray analysis

Phase set	No. of atoms	<i>R</i> *	Figure of merit
Isomorphous	—	—	0.46

$$R^* = \frac{\sum (F_{\text{obs}} - F_{\text{calc}})}{\sum F_{\text{obs}}} \quad R^\dagger = \frac{\sum (I_{\text{obs}} - I_{\text{mean}})}{\sum I_{\text{obs}}}$$

Fig. 1 Sequence of horse muscle phosphoglycerate kinase determined by ordering the 14 cyanogen bromide peptides on the X-ray map. The methionine residues that terminate each peptide are circled. The position and extent of the  $\alpha$ -helices and  $\beta$ -strands are indicated, using the same nomenclature as in Fig. 2.

group. This conformation can be seen in Fig. 4; it is quite different from the conformation observed in crystals of ATP<sup>18</sup>. Bound ADP has the same conformation as bound ATP.

The major interactions between the enzyme and the nucleotides are shown in Fig. 4. The adenine ring is almost completely buried in a deep, narrow slot. The amino group is innermost and probably makes a hydrogen bond with main-chain carbonyl of Leu 313. The adenine slot is lined by the main-chain segments that immediately follow  $\beta$ -strands G, H and J: Gly 212, Gly 213 and Ala 214; Gly 236, Gly 237 and Gly 238; and Val 339, Gly 340 and Val 341, giving the site a similar character to the aromatic specificity site of chymotrypsin<sup>19</sup>. The ribose is located in a shallow depression above the pyrrolidine ring of Pro 338. Ribose binding involves the side chain of Glu 343 which appears to move and stiffen to form hydrogen bonds with probably both the 2'- and 3'-hydroxyls of the sugar. The  $\alpha$ -phosphate group seems to make an ion-pair interaction with the charged  $\epsilon$ -amino group of Lys 219. The  $\beta$ - and  $\gamma$ -phosphates of ATP are located about 5 Å from the amino-terminus of helix 13, but do not interact with any side-chains. Hol *et al.*<sup>20</sup> have recently shown that the phosphate moieties of bound NAD, FAD and other phosphate-containing ligands, are similarly positioned in relation to helices in other enzymes, and suggest that there is a favourable ionic interaction between the negatively charged phosphates and the positive dipole at the N-termini of helices. It seems reasonable to conclude therefore that helix 13 in PGK acts as a phosphate-binding helix as suggested by Hol *et al.*<sup>20</sup>.

The binding of metal-ADP and -ATP complexes to PGK is accompanied by very similar small conformational changes in the vicinity of the binding site, and the only major difference between the interaction of the two nucleotides with the enzyme is in the location of the metal. Difference maps of the bound MgADP complex at 3 Å resolution in both sulphate and tartrate show a peak almost resolved from the main ADP density as shown in Fig. 3a. This peak coincides with the major peak in a

difference map at 6 Å resolution between MnADP and MgADP, and can therefore be reasonably ascribed to the metal ion. It is located about 4 Å from both the  $\alpha$ - and  $\beta$ -phosphates, and close to the carboxylate of Asp 374 as shown in Fig. 4. In contrast none of the difference maps of metal-ATP complexes shows a peak at this position (see Fig. 3b). Instead, difference maps of MnATP at 2.5 Å resolution and of MnATP-MgATP at 6 Å resolution show low peaks about 4 Å from the  $\gamma$ -phosphate. This evidence suggests that the metal may be associated with the  $\gamma$ -phosphate of ATP as shown in Fig. 4.

This X-ray picture of the nucleotide binding site on horse PGK is in excellent agreement with that produced for the yeast enzyme from the NMR studies of lanthanide ADP and ATP complexes<sup>21</sup>. The conformation of bound ATP revealed by both techniques is essentially similar, and the close cluster of three

Fig. 2 A drawing of the structure of the native horse muscle phosphoglycerate kinase molecule.  $\alpha$ -Helices are defined by cylinders and the  $\beta$ -strands by arrows which also denote their direction.

**Fig. 3** Equivalent two sections through the difference maps of *a*, MnATP at 2.5 Å resolution and *b*, MgADP at 3.0 Å resolution, approximately in the plane of the ribose and  $\alpha$ -phosphate (see Fig. 4). The adenine is below the plane to the left and the remaining phosphates above the plane to the right. The peak corresponding to the metal in ADP can be clearly seen, as can its absence from this position in ATP. Interchange of  $Mg^{2+}$  for  $Mn^{2+}$  has no effect on the metal position, nor on enzyme activity<sup>12</sup>.

histidines located by NMR can be reasonably identified with the equally close cluster containing His 62, His 169 and His 172 shown in Fig. 4 by their similar position relative to the nucleotides.

In contrast to PGK crystals in sulphate, which do not interact with 3-phosphoglycerate even at high concentrations<sup>2,3</sup>, the same crystals in tartrate exhibit large changes to their diffraction patterns at quite low concentrations of this substrate. However, difference maps calculated at 6 Å resolution reveal that the intensity changes are almost entirely accounted for by conformational changes that occur throughout the enzyme and most probably correspond to a rotation of the two domains relative to one another. Unfortunately it is not possible amongst the numerous peaks corresponding to the conformational change to identify any single peak as representing the bound substrate. A difference map calculated at 6 Å resolution of the ATP-3-phosphoglycerate ternary complex is similar to the sum of the difference maps of the two equivalent binary complexes.

### Possible mode of action

It would be expected that location and definition of the binding site for one substrate in a two-substrate enzyme such as PGK

would lead to the identification, at least in general terms, of the binding site of the second substrate, and the catalytic site. This is not so on either count for PGK, as an examination of Fig. 4 shows. ATP is bound with its  $\gamma$ -phosphate, which is transferred by the enzyme, in a region of the molecule almost devoid of functional groups, and almost completely exposed to the solvent. The amino acids closest to the  $\gamma$ -phosphate include two triple glycine sequences, residues 371–373 and 394–396, and Leu 399. The nearest functional groups, Arg 38, His 169, Lys 215 and Glu 403 are about 10 Å distant. In this environment it is very difficult to discover any plausible binding site for 3-phosphoglycerate sufficiently close to the ATP for direct transfer of the phosphoryl group to occur; or any functional groups close enough to the  $\gamma$ -phosphate of the ATP to catalyse the transfer; or finally, how water could be excluded from the vicinity of the  $\gamma$ -phosphate during the catalytic reaction.

There seem to be three possible explanations of this apparent paradox: (1) the observed ATP does not represent the phosphorylating nucleotide; (2) the observed domain geometry of the enzyme is an artefact of crystallisation; (3) the phosphoglycerate substrates bind at a site distant from the nucleotide site. Although in relation to the first possibility the presence of more than one substrate binding site has been proposed to explain the nonlinear kinetics of homologous yeast<sup>23</sup>, and human erythrocyte<sup>24</sup> enzymes (which may have a different origin as discussed later), the independent X-ray studies of the horse and yeast enzymes<sup>5</sup>, and NMR studies on the yeast enzyme<sup>21</sup> all reveal the same single binding site. The second possibility seems highly unlikely because yeast PGK, the crystal packing of which is quite different to the horse enzyme, exhibits the same disposition of domains<sup>6</sup>. The direct test of the third possibility, by the X-ray examination of complexes of the enzyme with phosphoglycerate, was inconclusive because the induction of extensive conformational changes obscured the binding site.

In the present absence of experimental evidence, we have examined the molecular structure for plausible phosphoglycerate binding sites. We have used the following criteria: (1) as at physiological pH, 3-phosphoglycerate carries three negative charges, and the more strongly bound 1,3-diphosphoglycerate four negative charges, it seems reasonable to suppose the presence of a cluster of basic residues in their binding site; (2) because X-ray analysis of enzymes has shown that substrates are almost always located in surface depressions, a cavity capable of accommodating the relatively small phosphoglycerates was

expected; (3) because there seems to be no catalytic residues near the  $\gamma$ -phosphate of the ATP, functional residues that could contribute to the catalysis may be located near the phosphoglycerate site. Using these criteria we found only one possible candidate for the binding site. This is shown in Fig. 4.

Fig. 5 Schematic drawing of the probable conformational changes in the substrate complexes of phosphoglycerate kinase suggested by the X-ray studies.

This site is located in the face of the N-terminal domain that opposes the ATP site on the C-terminal domain. The small cavity is located between the  $\beta$ -strands A and B and helix 6. Located within it and around it are five arginines, residues 21, 38, 65, 122 and 170; three histidines, residues 62, 169 and 172; two glutamates, residues 127 and 128; and aspartate, 23. Of these Arg 21 and Glu 127 are almost buried inside the cavity. This small region of the molecule contains half the arginine and histidine residues in the whole molecule. Note that in the NMR 'map' of the active site of yeast PGK<sup>21</sup>, the phosphoglycerate substrate is located further away from the ATP than the cluster of three histidines, which if identified with His 62, 169 and 172 of the horse enzyme, would place it in or near the cavity. If we assume that the observed structural homology between the yeast and horse enzymes extends to residues involved in substrate binding, the observation that at least one arginine takes part in the binding of 3-phosphoglycerate in the yeast enzyme<sup>26</sup> is also consistent with phosphoglycerate binding in the cavity.

If our tentative identification of the cavity with the phosphoglycerate site is correct, there is another problem to consider: as located on the native enzyme there must be a gap of about 10 Å between the  $\gamma$ -phosphate of the ATP and the carboxyl group of 3-phosphoglycerate that we presume must be closed when the phosphoryl group is catalytically transferred. Examination of the structure of the PGK molecule suggests that although each domain has a highly organised and apparently stable globular structure, the domain interface is small and not crossed by any of the secondary structures, suggesting that the enzyme is capable of a 'hinge-bending' conformational change. Consideration of Figs 2 and 4 shows that a rotation of 10–20° about a hinge located in or near the connection between  $\beta$ -strand F and helix 7 would be sufficient to bring the two domains, together with the ATP in its observed binding site, and the 3-phosphoglycerate in its proposed binding site, into contact, and at the same time to expel the solvent that lies between them. Residues 185 and 186 represent a Gly-Gly sequence at the C-terminus of  $\beta$ -strand F which could give the required degree of freedom at the appropriate position.

The 'hinge-bending' conformational change to PGK outlined above is illustrated in Fig. 5. We show the conformational change as occurring with the formation of phosphoglycerate

binary complexes, rather than with the formation of nucleotide binary complexes or ternary complexes, because our X-ray studies show that in the crystals in tartrate only small, local, conformational changes occur when ADP or ATP bind, whereas changes involving the whole molecule occur in the presence of 3-phosphoglycerate which are not increased in the ternary complex obtained by adding ATP. NMR studies of binary and ternary complexes of the yeast enzyme also show the same pattern of conformational change<sup>21</sup>, and studies on the rabbit muscle enzyme show that the reactivities of the seven sulphhydryl groups are affected to a greater extent by 3-phosphoglycerate than by ADP or ATP<sup>12</sup>. One consequence of the conformational change is the possibility that it could mediate in allowing the enzymatic activity to be modulated by substrates and non-substrates, giving rise to the nonlinear kinetics, and activation and inhibition phenomena that have been observed with the human<sup>23</sup> and yeast enzymes<sup>24,25</sup>, and which are otherwise difficult to reconcile with a monomeric enzyme. Although the 'hinge-bending' conformational change shown in Fig. 5 must be regarded as tentative until more information on the nature of binary and ternary enzyme-substrate complexes is obtained, it is consistent with most of the X-ray, NMR and chemical data discussed previously, some of which is difficult to understand in terms of a simple, monomeric enzyme.

Since preparing this paper we have become aware that Pickover *et al.*<sup>27</sup> have obtained direct evidence of a large conformational change in PGK from low angle X-ray studies of solutions of the yeast enzyme. They have found that the radius of gyration of the enzyme decreases by 1.09 Å on binding both ATP and 3-phosphoglycerate to form the ternary complex, but that binary complexes of these two substrates show much smaller decreases. Using the coordinates of the horse muscle enzyme they have interpreted the change in the radius of gyration in terms of a 'hinge-bending' conformational change of about 9–12° about a hinge located in the domain interface. Although the solution and crystal X-ray studies differ on whether the conformational change occurs on the formation of binary or ternary enzyme-substrate complexes, the proposed conformational changes are very similar: the illustration that Pickover *et al.*<sup>27</sup> provide of the enzyme after rotation of 12° about residue 187 (see Fig. 4) is extremely close to that which we have discussed above as being required to bring the observed ATP site and the proposed phosphoglycerate site together.

# Cloned fragments of the plasmid ColV,I-K94 specifying virulence and serum resistance

M. M. Binns, D. L. Davies & K. G. Hardy

Biological Laboratory, University of Kent at Canterbury, Canterbury, UK

*A cloned BamHI-generated fragment of ColV,I-K94 increased the virulence of Escherichia coli, causing an approximately 100-fold reduction in LD<sub>50</sub> for chicks. A genetic determinant for resistance to the bactericidal effects of serum was mapped to a 5,300 base-pair sequence within the fragment. Neither colicin V nor immunity to colicin V affected the pathogenicity of E. coli for chicks.*

STRAINS of *Escherichia coli* are an important cause of both diarrhoea and generalised infections in man and livestock<sup>1</sup>. Enteropathogenic strains causing diarrhoea are usually confined to the alimentary tract and often harbour conjugative plasmids specifying enterotoxins<sup>2</sup> and K88 (or K89) antigen<sup>3</sup> which enhance their pathogenicity. Smith<sup>4,5</sup> found that plasmids could also enhance the virulence of invasive strains responsible for generalised infections. Most of the *E. coli* strains responsible for independent cases of generalised infections in calves, lambs or chicks produced colicin V, a plasmid-determined antibacterial protein. Elimination of the ColV plasmids from human, bovine, ovine and avian strains of several different serotypes invariably reduced their pathogenicity for experimental animals. Re-introduction of ColV plasmids into the strains by conjugation restored their pathogenicity to its original level. These results demonstrated that ColV plasmids increased the invasiveness of *E. coli*, but as Smith pointed out<sup>4</sup>, did not indicate whether colicin V itself or some other products specified by the ColV plasmids were responsible. The antibiotic effects of colicin V, like those of other colicins, are confined largely to enterobacteria; colicin V is not toxic for animals<sup>6,7</sup>. However, the ecological significance of colicins is obscure (see ref. 8) and it remained possible that colicin V might increase the virulence of *E. coli*.

## Isolation and characterisation of ColV derivatives

The genetic determinants for virulence and for increased survival in serum, which are probably identical as discussed below, were mapped by isolating deletion mutants and point mutants of ColV, I-K94 and by cloning fragments of the plasmid into the plasmid vector pBR322 (ref. 9) by *in vitro* recombination procedures. The ColV derivatives were isolated in *E. coli* K-2 strains and were then transferred into a recently isolated *E. coli* strain which was more suitable for testing the effects of plasmids on the pathogenicity of *E. coli* for experimental animals.

ColV, I-K94 is a conjugative (F-like) plasmid<sup>10-12</sup> specifying colicin I as well as colicin V<sup>11</sup>. It was originally found in *E. coli* K94, a strain isolated from the stools of a patient suffering from a *Salmonella paratyphi* B infection (ref. 13 and P. Fredericq, personal communication). The positions of the genes specifying colicins and colicin immunity in ColV, I-K94 (pKH38) and in its derivative pKH46-1::γδ have been determined (D.L.D., M.M.B. and K.G.H., in preparation). The genetic and physical maps of ColV, I-K94 and the derivatives used here are shown in Fig. 1.

Most of the plasmids used in the pathogenicity tests were derived from pKH46-1::γδ, a *tra*<sup>-</sup> deletion mutant of ColV, I-

K94 (pKH38) specifying colicins V and I. pKH46-1::γδ has an insert of the 5.7-kilobase γδ insertion sequence<sup>14,15</sup> and was isolated after mobilisation of pKH46 by the F plasmid. The presence of the γδ sequence in pKH46-1::γδ and its derivatives increased the frequency with which these plasmids could be transferred by F mobilisation<sup>15</sup> into the strain used for testing pathogenicity and serum resistance. This was an essential feature of these plasmids as the strain used for these tests (KH933, serotype 078:K80) was a poor recipient in matings with either derepressed F-like or I-like plasmids and could not be transformed (<1 transformant per 100 μg of supercoiled pKH46-1::γδ DNA using the procedure described by Cohen *et al.*<sup>16</sup>).

Spontaneous deletion mutants of pKH46-1::γδ which specified no colicin V or only reduced titres occurred at a frequency of approximately 0.1%. The deletions in the two mutants used here had one end in common, namely the end of one of the 2.1-kilobase inverted repeats in pKH46-1::γδ (Fig. 1). The positions of the deletions were determined by electrophoresis of fragments generated by restriction endonucleases, as described in Fig. 1 legend, and from heteroduplexes formed between the deletion mutants and derivatives of pKH46-1::γδ which had insertions of the transposon Tn5 (ref. 17) which specifies kanamycin resistance. The positions of Tn5 in these plasmids are shown in Fig. 1. Plasmid

**Table 1** Colicin synthesis and immunity specified by derivatives of ColV, I-K94

Strain	Plasmid	Colicin titres		Colicin immunity	
		V	I	V	I
KH961	pKH46-1::γδ	64	512	+	+
KH974	pKH46-1::γδ Δ (7.4-25.6 kilobases)	<1*	512	+	+
KH982	pKH46-1::γδ Δ (7.4-29.3 kilobases)	—	256	—	+
KH962	pKH46-1::γδ <i>cia</i> -1	32	1	+	+
KH1020	pKH46-1::γδ 19.9kb::Tn5	64	256	+	+
KH1022	pKH46-1::γδ 19.9kb::Tn5 <i>cua</i> -1	<1	256	+	+
KH1069	pBH11	32	—	+	—
KH1070	pBH14	—	—	—	—
KH1071	pBR322: <i>Bam</i> HI-A	—	4096	—	+
KH1072	pBR322: <i>Bam</i> HI-C	<1*	—	+	—
KH1073	pBR322: <i>Hind</i> III-B	64	—	+	—
KH1074	pBR322: <i>Eco</i> RI-A	—	2048	—	+
KH932	ColV-B188	<1*	—	+	—
KH933	None	—	—	—	—

The host strain for all plasmids was KH933 (serotype 078:K80). For colicin titrations, broth cultures grown to  $A_{600} = 0.8$  were disrupted by sonication for 35 s (ref. 24). Serial twofold dilutions of the sonicates were made and 0.02-ml volumes of each dilution were dropped onto the surface of 25-ml nutrient agar plates (Oxoid blood agar base no. 2) containing streptomycin (200 μg ml<sup>-1</sup>) which had been overlaid with 3 ml of nutrient agar containing colicin-sensitive bacteria at a concentration of  $2.5 \times 10^8$  cells ml<sup>-1</sup>. Colicin I was assayed on plates overlaid with P1235 (ref. 37), a colicin V-tolerant mutant. Colicin V was assayed on plates overlaid with strain KH960, a colicin I-tolerant mutant of AB1157. Colicin titres are expressed as the highest dilution which inhibited growth of indicator bacteria. Colicin immunity was determined by streaking a loopful of broth culture (in exponential phase at  $2 \times 10^8$  cells ml<sup>-1</sup>) across a streak of colicin-producing bacteria (KH982 or KH1069) which had been grown for 24 h on nutrient agar, chloroformed and then overlaid with 3 ml of nutrient agar. Growth of colicin-immune bacteria (labelled +) was not inhibited over the streak. — Indicates absence of genetic determinant. Immunity to colicin I was tested using *E. coli* K-12 (W3110) as a host strain since KH933 is resistant to colicin I.

\* These strains produced no detectable colicin V in broth cultures, but 48-h colonies on nutrient agar plates formed small inhibition zones when chloroformed and overlaid with strain KH960.

† Growth was partially inhibited by colicin V.

**Fig. 1** Physical and genetic maps of ColV, I-K94 and its derivatives. *a*, ColV, I-K94 (pKH38). The positions of inverted repeat sequences (shown as open boxes) and of sequences homologous to the F plasmid in pKH38/F heteroduplexes (shown as thicker lines) were determined by electron microscopy of plasmid DNA (D.L.D., M.M.B. & K.G.H., in preparation). Coordinates in pKH38 (total length 124.2 kilobases) were defined, as described by Sharp *et al.*<sup>32</sup>, with reference to the 0.8-kilobase insertion/deletion loop at 87.1 F in pKH38/F heteroduplexes. ColV, I-K94 (pKH38) differs from the ColV, I-K94 molecules examined by Sharp *et al.*<sup>32</sup> in the number and arrangement of 1.3-kilobase inverted repeat sequences and in not forming an insertion/deletion loop at 58.0 F in pKH38/F heteroduplexes. The *tra* region comprises the sequence which is homologous (as determined by heteroduplex analysis in the conditions described by Sharp *et al.*<sup>32</sup>) to the F plasmid sequence 62.0 F–93.2 F which is essential for conjugation<sup>33,34</sup>. Part of the ColV, I-K94 sequence which is homologous to the *traI* gene of the F plasmid occurs in pKH46-1:: $\gamma\delta$  as indicated in *b*. The *traI* gene of F maps within the homologous sequence indicated by dotted lines; the box represents the length of DNA sequence required to code for the protein specified by *traI* which has a molecular weight of 174,000 (ref. 34). *a,a'* Is an inverted repeat sequence of  $1.3 \pm 0.09$  kilobases; *b<sub>1</sub>,b<sub>2</sub>,b'* are three homologous sequences of  $0.8 \pm 0.08$  kilobases, two of which have the same orientation. *b*, pKH46-1:: $\gamma\delta$  is a deletion mutant of pKH38. The genes specifying colicin V (*cva*), immunity to colicin V (*cvi*), colicin I (*cii*), immunity to colicin I (*cii*) and increased survival in serum (*iss*) map within the regions indicated. The *cvi* gene maps to the left of *cva* as drawn, but the maximum limit of *cvi* to the right has not been determined. The positions of genes specifying colicins were determined from the analysis of cloned fragments and the relationship of pKH46-1:: $\gamma\delta$  to pKH38 was determined by heteroduplex analysis (D.L.D., M.M.B. & K.G.H., in preparation). The pKH46-1:: $\gamma\delta$  2.7–5.3-kilobase sequence is homologous to the sequence between the 1.3-kilobase inverted repeat sequence (*a,a'*) in pKH38, but in pKH46-1:: $\gamma\delta$  it is flanked by a  $2.1 \pm 0.1$ -kilobase inverted repeat sequence. The remaining 37 kilobases of pKH46-1:: $\gamma\delta$  (with the exception of the  $\gamma\delta$  insert) are homologous to the pKH38 90.4–121.7-kilobase sequence. pKH46-1:: $\gamma\delta$  coordinates are assigned from the end of one of the 2.1-kilobase inverted repeats. Copies of the Tn5 transposon were added to pKH46-1:: $\gamma\delta$  by mobilisation of the plasmid with *F'*<sub>lac</sub><sup>+</sup> (ref. 21) from a donor lysogenic for the bacteriophage  $\lambda$ b<sub>513</sub>b<sub>519</sub>x<sub>156</sub>Cl<sub>857</sub>S<sub>7</sub>rex::Tn5 (ref. 17) to a *recA*<sup>+</sup> recipient in matings at 30 °C. Two recipients selected for expression of kanamycin resistance at 42 °C harboured plasmids with Tn5 insertions at the positions indicated. *c* and *d* are deletion mutants, pKH46-1:: $\gamma\delta$   $\Delta$  (7.4–25.6 kilobases) and pKH46-1:: $\gamma\delta$   $\Delta$  (7.4–29.3 kilobases). Restriction endonuclease sites within pKH46-1:: $\gamma\delta$  and its derivatives (*e*) were determined by electrophoresis of fragments generated by complete or partial digestion with restriction endonucleases (Boehringer) used either alone or in combination. Restriction endonuclease reactions were carried out for 15 min at 37 °C in 50- $\mu$ l volumes containing approximately 0.5  $\mu$ g DNA in the following buffers: 100 mM Tris-HCl (pH 7.5), 50 mM NaCl, 10 mM MgCl<sub>2</sub> (for *Eco*RI); 10 mM Tris-HCl (pH 7.6), 50 mM NaCl, 10 mM MgCl<sub>2</sub>, 14 mM dithiothreitol (for *Hind*III); 6 mM Tris-HCl (pH 7.5), 20 mM KCl, 6 mM MgCl<sub>2</sub>, 6 mM dithiothreitol (for *Bam*HI). Fragments were analysed by electrophoresis through horizontal slab gels containing 0.8% (w/v) agarose and ethidium bromide (0.5  $\mu$ g ml<sup>-1</sup>) in Tris-borate buffer<sup>35</sup> at 60 V for 18 h at room temperature. Small fragments were analysed by polyacrylamide gel electrophoresis as described by Bolivar *et al.*<sup>9</sup>. Fragments of  $\lambda$ Cl<sub>857</sub>S<sub>7</sub> DNA generated by *Eco*RI and *Hind*III were included in gels as molecular weight standards<sup>36</sup>. Fragments of pKH46-1:: $\gamma\delta$  were ligated to pBR322 (ref. 9) in a reaction mixture containing 0.066 mM ATP, 66 mM Tris-HCl (pH 7.6), 6.6 mM MgCl<sub>2</sub>, 10 mM dithiothreitol, 1 unit T4 DNA ligase (Bethesda Research Laboratories) and 1  $\mu$ g of restriction endonuclease-cleaved plasmid DNA in a total volume of 50  $\mu$ l. After incubation for 4 h at 20 °C, recombinant plasmids were selected from the mixture by transformation<sup>16</sup> and selection on nutrient agar plates containing ampicillin at a concentration of 120  $\mu$ g ml<sup>-1</sup>. Experiments involving recombinant plasmids were carried out in Class I conditions as defined by the Williams report (Cmnd 6600).

pKH46-1:: $\gamma\delta$   $\Delta$  (7.4–25.6 kilobases) specified greatly reduced titres of colicin V and immunity to colicin V (Table 1) and pKH46-1:: $\gamma\delta$   $\Delta$  (7.4–29.3 kilobases) specified no colicin V or immunity to colicin V. A point mutant of pKH46-1:: $\gamma\delta$  19.9kb::Tn5 (pKH46-1:: $\gamma\delta$  containing the Tn5 transposon at the 19.9-kilobase position) which did not specify the synthesis of colicin V, was obtained by treating plasmid DNA at 37 °C for 24 h with 0.4 M hydroxylamine in the presence of 1 mM EDTA as described by Tessman<sup>18</sup>. A kanamycin-resistant transformant which did not specify colicin V synthesis (*Cva*<sup>-</sup>) was selected. The fragments of pKH46-1:: $\gamma\delta$  19.9kb::Tn5 *cva*-1 generated by *Eco*RI and by *Hind*III were identical to those of pKH46-1:: $\gamma\delta$  19.9kb::Tn5.

Fragments of pKH46-1:: $\gamma\delta$  obtained by digestion with restriction endonucleases *Eco*RI, *Hind*III or *Bam*HI were cloned in the plasmid vector pBR322 (ref. 9) as described in Fig. 1 legend. Recombinant plasmids containing the following fragments were isolated: *Eco*RI-A, *Bam*HI-A, *Bam*HI-C and *Hind*III-B. In addition, part of the *Hind*III-B fragment, comprising the 22.6–30.7-kilobase sequence of pKH46-1:: $\gamma\delta$ , was cloned in pBR322 to form pBH11. pBH11 was obtained as a transformant from a *Hind*III-digested preparation of pKH46-1:: $\gamma\delta$  which was incubated with T4 DNA ligase in the presence of *Hind*III-digested pBR322. However, pBH11 was found to

have only one *Hind*III site although it specified both colicin V synthesis and ampicillin resistance. Analyses of restriction endonuclease digests of pBH11 and of the heteroduplexes pBH11/pBR322 and pBH11/pKH46-1:: $\gamma\delta$  19.9kb::Tn5 established that the entire pBR322 sequence, but only part of the *Hind*III-B fragment, was present in pBH11. The orientation of the fragment in pBH11 was the same as in the plasmid in which the entire *Hind*III-B fragment had been cloned, that is, the sequence derived from the  $\gamma\delta$  insert (29.2–30.7 kilobases) was adjacent to the closely linked *Hind*III and *Eco*RI sites of pBR322. pBH14 was derived from pBH11 by ligating a 7.5-kilobase *Eco*RI-generated fragment of pBH11; it comprises the 22.6–25.8 kilobase sequence of pKH46-1:: $\gamma\delta$  and the pBR322 plasmid sequence with the exception of the 31-base pair sequence between the *Eco*RI and *Hind*III sites of pBR322.

### Transfer of cloned fragments and ColV mutants to an invasive strain by mobilisation

To determine their effects on the pathogenicity of *E. coli* for chicks, ColV derivatives were transferred by conjugation into strain KH933, a Col<sup>-</sup> derivative of *E. coli* B188. *E. coli* B188 was isolated from a calf suffering from a generalised infection and has the serotype 078:K80 (ref. 4), the most common

serotype among *E. coli* strains responsible for generalised infections in livestock<sup>1,4</sup>. The ColV plasmid originally present in *E. coli* B188 was cured by treatment of the strain with acridine orange<sup>19</sup> and its absence from the Col<sup>-</sup> derivative, KH933, was confirmed by dye-buoyant density centrifugation<sup>20</sup>. KH933 was chosen as the host strain for ColV derivatives so that the results of the pathogenicity tests could be compared with published data on the effects of other ColV plasmids<sup>4,5</sup>. Furthermore, the effects of plasmids on a strain known to be a potential pathogen would be more significant than their effects on the pathogenicity of a strain such as *E. coli* K-12 which kills experimental animals only when given in huge doses.

Plasmid pKH46-1:: $\gamma\delta$  and its derivatives which also comprised a copy of the  $\gamma\delta$  insertion sequence were transferred from auxotrophic *E. coli* K-12 donors using F<sub>10114</sub>lac<sup>+</sup> (ref. 21) as a mobilising plasmid in 8-h matings in broth at 30 °C. Recipients were selected on glucose-minimal salts agar<sup>22</sup> containing kanamycin at a concentration of 25  $\mu\text{g ml}^{-1}$  or colicin V (produced by a lawn of ColV<sup>+</sup> bacteria which was chloroformed after 18 h of growth, overlaid with 10 ml of agar and incubated for 4 h at 37 °C before being used for selection). F<sup>-</sup>Col<sup>+</sup> derivatives of the recipients were isolated from broth cultures which had been grown at 42 °C. Plasmid pKH46-1:: $\gamma\delta$   $\Delta$  (7.4–29.3 kilobases) was isolated as a spontaneous mutant from a KH933 strain harbouring pKH46-1:: $\gamma\delta$ .

Derivatives of pBR322 were transferred to KH933 from *E. coli* K-12 donors which also harboured the I-like conjugative plasmid R144drd3 (ref. 23) and the non-conjugative plasmid ColK-K235 (ref. 24). ColK-K235 provided the *trans*-acting mobility determinant<sup>25</sup> which is essential for efficient mobilisation of pBR322 derivatives by R144drd3. Matings were interrupted after 5 min. Approximately 25% of recipients selected on plates containing ampicillin at a concentration of 120  $\mu\text{g ml}^{-1}$  were ColK<sup>+</sup> and R<sup>+</sup>. Colicin titres specified by ColV derivatives in the host strain KH933 are listed in Table 1.

Table 2 Effect of ColV derivatives on the pathogenicity of *E. coli*

Strain	Plasmid	LD <sub>50</sub> ( $\pm$ s.e.m.) $\times 10^{-5}$
KH932	ColV-B188	2.4( $\pm$ 2.4)
KH961	pKH46-1:: $\gamma\delta$	2.1( $\pm$ 1.1)
KH962	pKH46-1:: $\gamma\delta$ <i>cia</i> -1	2.0( $\pm$ 2.1)
KH1020	pKH46-1:: $\gamma\delta$ 19.9kb::Tn5	1.0( $\pm$ 1.7)
KH1071	pBR322: <i>Bam</i> HI-A	1.8( $\pm$ 1.8)
KH1022	pKH46-1:: $\gamma\delta$ 19.9kb::Tn5 <i>cva</i> -1	6.2( $\pm$ 3.2)
KH974	pKH46-1:: $\gamma\delta$ $\Delta$ (7.4–25.6 kilobases)	220( $\pm$ 170)
KH982	pKH46-1:: $\gamma\delta$ $\Delta$ (7.4–29.3 kilobases)	490( $\pm$ 240)
KH1069	pBH11	380( $\pm$ 200)
KH1070	pBH14	180( $\pm$ 140)
KH1075	None	320( $\pm$ 120)
KH933	None	190( $\pm$ 180)

Pathogenicity was tested by injecting appropriate dilutions of broth cultures intramuscularly into 1-d-old chicks. For each strain, 14 chicks were injected at each of three or four concentrations of bacteria, ranging in 10-fold increments from 10<sup>5</sup> to 10<sup>8</sup> viable cells. Survival was recorded after 7 days. LD<sub>50</sub> values  $\pm$  s.e.m. were calculated by probit analysis as described by Finney<sup>26</sup>. KH1075 is a derivative of KH1069 which had spontaneously lost pBH11.

## Pathogenicity of strains for chicks

Pathogenicity tests of strains for 1-d-old chicks (Table 2) showed that neither of the deletion mutants of pKH46-1:: $\gamma\delta$  nor pBH11, which specified high levels of colicin V, affected the pathogenicity of KH933. However, pBR322 linked to the *Bam*HI-generated fragment A (subsequently referred to as pBR322:*Bam*HI-A), which specified neither colicin V nor immunity to colicin V, increased the pathogenicity of KH933 as much as did pKH46-1:: $\gamma\delta$ , pKH46-1:: $\gamma\delta$  19.9kb::Tn5, pKH46-1:: $\gamma\delta$  *cia*-1 or ColV-B188. All these plasmids produced an approximately 100-fold decrease in the LD<sub>50</sub> of strain KH933 for 1-d-old chicks. The mutation in pKH46-1:: $\gamma\delta$  19.9kb::Tn5 *cva*-1 which affected colicin V synthesis did not significantly affect the ability of the plasmid to increase the

virulence of *E. coli*. As pBR322:*Bam*HI-A increased pathogenicity but pKH46-1:: $\gamma\delta$   $\Delta$  (7.4–25.6 kilobases) did not, the virulence determinant can be mapped to the 7.4–24.3-kilobase sequence in pKH46-1:: $\gamma\delta$  and to the 104.8–121.7-kilobase sequence in ColV, I-K94 (pKH38). The slopes of the dose-response curves for all the strains tested were not significantly different; the ratios of the LD<sub>50</sub> values can therefore be used to compare the pathogenicity of strains.

## Survival of strains in serum

Smith<sup>4</sup> found that ColV<sup>+</sup> strains survived better in a variety of animal sera than did their Col<sup>-</sup> counterparts. Strains harbouring ColV derivatives were therefore examined to determine the position of the genetic determinant for increased survival in serum (*iss*). We used fresh rabbit serum, but Smith<sup>4</sup> has previously shown that ColV plasmids also enhance survival in chicken serum. In addition to the plasmids used in the pathogenicity tests, the effects of the cloned fragments, *Hind*III-B, *Eco*RI-A and *Bam*HI-C, on the survival of KH933 in rabbit serum were examined. Of the 14 plasmids tested, the following did not affect the survival of KH933 in fresh serum: pKH46-1:: $\gamma\delta$   $\Delta$  (7.4–25.6 kilobases), pKH46-1:: $\gamma\delta$   $\Delta$  (7.4–29.3 kilobases), pBR322, pBH14, pBR322:*Eco*RI-A, pBR322:*Bam*HI-C. pBH11 caused a small but significant increase in survival (Fig. 2). The following plasmids greatly increased the survival of KH933 in serum: pKH46-1:: $\gamma\delta$ , pKH46-1:: $\gamma\delta$  19.9kb::Tn5, pKH46-1:: $\gamma\delta$  *cia*-1, pKH46-1:: $\gamma\delta$  19.9kb::Tn5 *cva*-1, pBR322:*Hind*III-B, pBR322:*Bam*HI-A and ColV-B188. All these plasmids produced a similar increase in serum resistance, with the exception of pBR322:*Bam*HI-A, which was more effective than any of the others (Fig. 2). pBR322 is a multi-copy plasmid<sup>9</sup>; the high level of serum resistance specified by pBR322:*Bam*HI-A may therefore result from multiple copies of the *iss*<sup>+</sup> determinant. The titres of colicin I specified by pBR322:*Bam*HI-A were eightfold greater than those specified by pKH46-1:: $\gamma\delta$  (Table 1). A strain harbouring both pBH14 and pKH46-1:: $\gamma\delta$  survived as well in serum as did a strain harbouring only pKH46-1:: $\gamma\delta$ . All derivatives of KH933 grew equally well in rabbit serum in which complement had been inactivated by heating to 56 °C for 30 min.

The effects of ColV derivatives on the survival of bacteria in serum are therefore correlated with their effects on pathogenicity; only plasmids which greatly increased the survival of KH933 in serum enhanced the pathogenicity of the strain for chicks.

Both pBR322:*Hind*III-B and pBR322:*Bam*HI-A increased the survival of KH933 in serum, so the *iss*<sup>+</sup> determinant maps within the 5.3-kilobase sequence at 19.0–24.3 kilobases in pKH46-1:: $\gamma\delta$ . Within this region, neither the 19.0–21.0-kilobase sequence nor the 22.6–24.3-kilobase sequence encodes all the information required for expression of the *iss*<sup>+</sup> determinant, as neither pBH11 (containing the 22.6–30.7 kilobase fragment) nor pBR322:*Eco*RI-A greatly increased survival in serum. In addition, introduction of the Tn5 transposon at the 19.9-kilobase position does not affect the serum resistance or the increased virulence conferred by pKH46-1:: $\gamma\delta$ .

Seven of the ColV derivatives were also examined for their effects on the survival of *E. coli* K-12 in serum. All *E. coli* K-12 strains harbouring derivatives of pKH46-1:: $\gamma\delta$  were killed much more rapidly by fresh rabbit serum than were derivatives of KH933. However, plasmids which increased the pathogenicity and the serum resistance of KH933 also increased the survival of *E. coli* K-12 (strain W3110). The survival of *E. coli* K-12 strains was tested as described in Fig. 2 legend, except that bacteria were added to serum at an initial concentration of 10<sup>7</sup> ml<sup>-1</sup>. All the following plasmids produced a similar increase in the survival of W3110 in fresh rabbit serum: pKH46-1:: $\gamma\delta$ , pKH46-1:: $\gamma\delta$  19.9kb::Tn5, pKH46-1:: $\gamma\delta$  19.9kb::Tn5 *cva*-1. None of the following plasmids increased the survival of *E. coli* K-12 in serum: pKH46-1:: $\gamma\delta$   $\Delta$  (7.4–25.6 kilobases), pKH46-1:: $\gamma\delta$   $\Delta$  (7.4–29.3 kilobases), pBH11, pBH14. For example, the

**Fig. 2** Survival of bacteria in serum. Cells from exponentially growing broth cultures at  $A_{400} = 0.4$  were collected by centrifugation and resuspended in an equal volume of 0.85% (w/v) NaCl. The suspension was diluted 100-fold in 0.85% (w/v) NaCl and then 10-fold in fresh rabbit serum. Rabbit serum was kept at  $-20^{\circ}\text{C}$  after collection and was used within 18 h. All strains were tested simultaneously using the same batch of serum. The suspension of bacteria in serum was incubated at  $37^{\circ}\text{C}$  and viable counts were made at intervals by spreading 0.2-ml volumes of appropriate dilutions onto the surfaces of nutrient agar plates (Oxoid blood agar base no. 2). The value at each point is the mean  $\pm$  s.e.m. of three independent determinations using the same batch of serum. Each of the three determinations was the mean of three spread plates. The strains are KH933 (▲), and KH933 harbouring the plasmids pBR322:BamHI-A (●), pKH46-1:: $\gamma\delta$  (■) and pBH11 (▼).

fractions of strain W3110 (pKH46-1:: $\gamma\delta$ ) surviving in serum after 30 and 60 min were  $6.4 \times 10^{-2}$  and  $2.9 \times 10^{-2}$ . Comparable values for a W3110 strain which did not harbour a plasmid were  $7 \times 10^{-3}$  and  $3.1 \times 10^{-4}$ .

### Implications of findings: close linkage of genes specifying colicin V and virulence

The correlation between the increased pathogenicity and the increased serum resistance specified by the ColV derivatives examined here strongly suggests that the primary reason for the increased virulence of bacteria harbouring ColV plasmids is that they are less sensitive to host defence mechanisms dependent on antibody and complement. The determinants for serum resistance and for colicin V are closely linked in ColV, I-K94; the *iss*<sup>+</sup> determinant maps within the pKH46-1:: $\gamma\delta$  19.0–24.3-kilobase sequence and the genes specifying colicin V and immunity to colicin V map within the 25.6–29.2-kilobase sequence (Fig. 1).

The presence of a ColV plasmid which increases virulence is not, of course, the only factor which is required to convert an otherwise benign strain of *E. coli* (such as *E. coli* K-12) into an invasive strain. Nonetheless, the high frequency of colicin V producers among *E. coli* strains responsible for recent cases of generalised infections in livestock<sup>4</sup> suggests that it is an important factor. The occurrence of the virulence determinant on plasmids specifying colicin V is not confined to recently isolated plasmids from animal sources. The ColV, I-K94 plasmid used here was isolated from a patient in 1948. The first colicin to be investigated, by Gratia<sup>26</sup>, was produced by a strain called *E. coli* V because of its virulence for rabbits and guinea pigs (the strain was isolated from the blood of an infected

rabbit), suggesting that the ColV-CA7 plasmid present in *E. coli* V also has the virulence determinant.

The frequent occurrence of the genes for colicin V and for virulence on the same plasmid, and their close linkage in ColV, I-K94, suggest that they may interact to their mutual selective advantage. The nature of any such interaction is, however, obscure, as is the ecological significance of colicins<sup>8</sup>. Several ColV plasmids increase the ability of *E. coli* strains to survive in the human alimentary tract<sup>4,5</sup>, but this does not result from the bactericidal effects of colicin V<sup>5</sup>. It may be another effect of the *iss*<sup>+</sup> determinant. The association between the genes specifying colicin V and virulence in ColV plasmids resembles the relationship between genes specifying raffinose utilisation and K88 antigen, in that almost all plasmids specifying K88 antigen, which aids colonisation of the small intestine by enteropathogenic strains, also specify raffinose utilisation, which is apparently unrelated to virulence<sup>27</sup>. However, these two genetic determinants are not closely linked in at least one plasmid; in pRI8801 they are about 30 kilobases apart<sup>28</sup>.

Whatever the reason for the relationship between the genes specifying colicin V and virulence on ColV plasmids, colicin V production may be a useful indicator of the presence of the virulence determinant in *E. coli* strains. It may be significant, for example, that colicin V is the type of colicin most frequently produced by *E. coli* strains responsible for urinary tract infections in hospitalised patients<sup>29</sup>. Other reports<sup>30</sup> indicate that colicin V may be more commonly produced by strains responsible for a variety of human extra-intestinal infections than by strains isolated from the faeces of healthy people. However, the results reported here show that the virulence determinant of ColV, I-K94 is effective in the absence of genes specifying colicin V and immunity to colicin V. It may therefore be more widespread than is indicated by the frequency of colicin V production. Plasmids which do not specify colicin V but which increase the resistance of *E. coli* to the bactericidal effects of human serum have been described (see ref. 31). It is not known whether these plasmids also increase virulence.

We thank Dr H. Williams Smith for valuable discussions and for testing the pathogenicity of strains. This work was supported by a project grant from the MRC.

## Soft X-ray emission from the vicinity of the dwarf nova AY Lyrae

THE discovery of a low-intensity soft X-ray source in a region of the sky containing the dwarf nova AY Lyrae is reported here. Figure 1 shows how the source, designated H1839+37, appeared in the superposition of HEAO A2 scanning data that were taken on 9 October 1977 with the low-energy detector LED1. (A complete description of the A2 experiment on HEAO 1 is given by Rothschild *et al.*<sup>1</sup>.) The source was detected only in the energy interval 0.18–0.43 keV. The peak in Fig. 1 represents an intensity of  $0.014 \pm 0.0027$  counts  $\text{cm}^{-2} \text{s}^{-1}$  ( $5\sigma$ ). An upper limit to the temperature of H1839+37 was derived by comparing the ratio of the source counts in different energy bands. If a thermal bremsstrahlung spectrum is assumed,  $T_{\text{BR}} \leq 5 \times 10^6$  K, whereas a black-body fit implies  $T_{\text{BL}} \leq 1.4 \times 10^6$  K. A lower limit  $T_{\text{BL}} \geq 1 \times 10^5$  K is set by the LED1 lower-level discriminator.

The region of the sky containing H1839+37 was scanned by HEAO 1 for several days. The light curve for the entire October 1977 observation is shown in Fig. 2a. Each point is the superposition of 1–5 individual scans made on a given day. For a half day, over which the spin axis of the satellite is held fixed, an estimate of the variability of H1839+37 can be made independently of knowing the exact source position, that is, without requiring corrections for the transmission of the LED1 collimator. Applying a  $\chi^2$  test to the five 9.5–10.0 scans for October (not shown here), the source is found to be constant at only the 10% confidence level ( $\chi^2 = 7.68$  for 4 d.f.). The source is definitely variable on longer time scales because when it was observed 6 months later it was not detected, even in a superposition of 5.5 days of scanning data. The upper limit to the intensity for that observation (7–12 April 1978) is 0.005 counts  $\text{cm}^{-2} \text{s}^{-1}$ .

The centroid of the position error box for H1839+37 is at  $\alpha = 18 \text{ h } 38 \text{ min } 58 \text{ s}$ ,  $\delta = +37^\circ 52.4'$  (1950 epoch). The error box, shown in Fig. 3, excludes the bright star Vega ( $\alpha$  Lyrae).

**Fig. 1** Part of the data from a superposition of soft X-ray (0.18–0.43 keV) scans on 9 October 1977. The intensity of the source at scan angle  $61^\circ$  was determined by making a least squares fit (the smooth line) to the data. The fitting procedure took into account the triangular response of the collimator, which had a  $1.5^\circ$  field of view (FWHM) in the scan direction. The area of the detector was  $174 \text{ cm}^2$ .

**Fig. 2** a, The soft X-ray light curve of H1839+37 for October 1977. b, Same as (a), corrected for a source at the position of AY Lyr. c, The AAVSO visual light curve for AY Lyr covering the HEAO 1 observation.

Also shown is the slightly overlapping error box for 4U1852+37, a hard X-ray source with an intensity of  $0.57 \pm 0.15$  Uhuru flux units (UFU) (ref. 2 and Jones, personal communication). The HEAO A2 upper limit for hard X-ray emission from either H1839+37 or 4U1852+37 is  $1/3$  UFU (Swank, personal communication).

H1839+37 was discovered in a survey of  $\sim 130$  cataclysmic variable stars<sup>3</sup>; it corresponds to the position of one of the members of this class—the dwarf nova AY Lyrae. Three other dwarf novae have been identified with soft X-ray sources: SS Cygni, EX Hydrae, and U Geminorum. This, plus the fact that a search in the H1839+37 error box has revealed no other promising candidates, make AY Lyr seem like a possible counterpart for H1839+37.

AY Lyr belongs to the subset of dwarf novae that have both normal outbursts and super outbursts<sup>4</sup>. Patterson<sup>4</sup> reports that the quiescent visual brightness of the system is  $V > 18$ . At the time of the HEAO 1 sighting on 9 October 1977, AY Lyr was at  $V > 14.8$  (Mattei, personal communication). Assuming a flat response across the LED1 bandwidth (0.18–0.43 keV), the 0.25 keV flux from a source at the position of AY Lyr is  $\sim 1 \times 10^{-11} \text{ erg cm}^{-2} \text{s}^{-1}$ . The ratio of the X-ray to optical flux for the other dwarf novae in quiescence is  $\leq 1$  (ref. 3). For AY Lyr, this ratio does not exceed unity only if the dwarf nova was as

bright as  $V \sim 15$  during the HEAO 1 observation. In Fig. 2b the October 1977 light curve of H1839+37 has been corrected for a source at the position of AY Lyr, taking into account the transmission of the LED1 collimator. A comparison of the X-ray light curve with the AAVSO visual light curve for AY Lyr, which is shown in Fig. 2c, reveals that there was no increase in the X-ray activity during a short optical outburst of the dwarf nova<sup>5</sup>. There were only three LED1 scans during the October outburst; these occurred 0.4–0.6 d after the beginning of the outburst. A short visual outburst also occurred on 9 April 1978 when AY Lyr was again being scanned by HEAO 1 (ref. 5), but no X rays were detected from the object at that time either.

Part of the difficulty in interpreting this observation is in not having a good measurement of the X-ray spectrum of H1839+37. The dwarf novae detected as X-ray sources seem to have two very different spectral components: a medium or hard X-ray ( $E > 0.5$  keV) component which fits a thermal bremsstrahlung model with line emission<sup>6</sup>, and a soft X-ray ( $E < 0.5$  keV) component whose spectrum may fit any of several models<sup>3</sup>. The relative intensities of both components are correlated with the dwarf nova optical outburst. The soft component increases with increasing visual brightness, but the optically thin component is not uniquely correlated: in SS Cyg this component dramatically decreases during outburst<sup>7</sup>, while in U Gem the converse is observed<sup>8</sup>. In addition, the range of temperatures for the 'hard' component spans an order of magnitude: from  $\sim 20$  keV for SS Cyg to  $\sim 5$  keV for EX Hya and U Gem (refs 6 and 8). Therefore, with so few examples and such a wide range of behaviour, it is not difficult to envisage a behaviour pattern for H1839+37 which is consistent with the X-ray behaviour of dwarf novae.

For example, in AY Lyr variable accretion onto a white dwarf primary could account for X-ray flaring during quiescence. If the spectrum were optically thin, then absorption by increased in-falling material during outburst could produce a decrease in the bremsstrahlung X rays (an effect similar to that observed in SS Cyg during outburst). The bright soft X-ray excess observed in SS Cyg during outburst may not appear in AY Lyr because the boundary layer between the white dwarf and the compact star in AY Lyr may not get hot enough to radiate soft X rays. Differences in mass accretion rates during quiescence and outburst among all the dwarf novae may account for the range of observed behaviour.

Our intention has been simply to point out a correspondence in the positions of the soft X-ray emitter H1839+37 and the

dwarf nova AY Lyr, and to present all the pertinent data on both the X-ray and optical sources. Note that a search for a set of 130 randomly distributed error boxes ( $\sim 0.6^\circ \times 6^\circ$  in size), such as the cataclysmic variable survey, would have about a 40% chance of producing a positional coincidence with one or more of the  $\sim 50$  soft X-ray sources in the HEAO A2 Catalogue (in preparation). Thus there was a relatively high expectation of finding one fortuitous association of an X-ray source with a cataclysmic variable. If H1839+37 has a 'steady' emission even a factor of 10 below the HEAO 1 threshold, the X-ray telescope on the recently launched Einstein Observatory (HEAO 2) should be able to locate it accurately.

We thank Ms J. Mattei and the other members of the AAVSO for the October 1977 light curve of AY Lyr, Drs P. Szkody and K. Mason and the anonymous referee for their helpful criticisms, J. Patterson for his recent observations of AY Lyr, and J. Boyer for typing. This work was supported by NASA contract NAS 5-25049.

## Drift rates of Jupiter's S-bursts

THE average drift rates of Jupiter's S-bursts observed in the 21–23 MHz frequency range depend on the jovian declination of the Earth,  $D_E$  (ref. 1). The fact that the values obtained by other observers at higher and lower frequencies also seemed to agree with this observation was interpreted as either being coincidental or implying that the drift rates may not depend on frequency. Here I present new drift rate measurements at 21–23 MHz obtained in 1978, bringing the total number of individual measurements in 1974–78 to over 12,000.

The dynamic spectra of bursts were recorded on 16-mm film in real time with a 48-channel radio spectrograph. The S-spectra show a wide variety of forms<sup>2</sup>. The simplest bursts appear as lines tilted in the orthogonal time-frequency plane. Samples of such events, from which drift rates are measured, are shown in Fig. 1. The samples illustrate the fact that the instantaneous bandwidth of bursts can vary considerably while the drift rate remains essentially the same.

All the simple bursts are observed to have a negative frequency drift. The rate varies from burst to burst and from group to group. The spread in rates within a storm is, as a rule, relatively large. The average drift rates do not seem to be related to the central meridian longitude (CML) of Jupiter or to Io's geocentric phase<sup>1,2</sup>. The instantaneous bandwidths, however, tend to be larger at the high-longitude edges of region B. The S-bursts occur only in the Io-related regions B and C (refs 2, 3).

The mean drift rates for B-region storms observed in 1974–78 are plotted as a function of  $D_E$  in Fig. 2. As can be seen, the rates change from approximately  $-30 \text{ MHz s}^{-1}$  to  $-20 \text{ MHz s}^{-1}$  as  $D_E$  decreases from  $3.3^\circ$  to  $0.5^\circ$ . It is now obvious that the drift rates in the vicinity of  $-10 \text{ MHz s}^{-1}$  which were obtained at other low values of  $D_E$  (refs 1, 4) must have been due to the lower observation frequency used, suggesting that the drift rates of S-bursts in region B are proportional to both  $D_E$  and frequency.

Fig. 3 H1839+37 error box (90% confidence), also showing the positions of Vega, the dwarf nova AY Lyr, and the error box for a 4U source.

**Fig. 1** Samples of high-resolution dynamic spectra of jovian S-bursts. Time increases from left to right. The instantaneous bandwidths of the bursts in *a* are 50 kHz or less, the bandwidths of certain bursts in *b* are a few hundred kHz, and those in *c* vary from 50 kHz to 1 MHz.

**Fig. 2** Mean drift rates of S-bursts observed in storms of region B, plotted as a function of the jovicentric declination of the Earth. Each circle represents one storm, its size denoting the number of measurements.

If the mean drift rates of S-bursts in region C are plotted as a function of  $D_E$ , no clear dependence on  $D_E$  is evident. This is illustrated in Fig. 3, comprising storms observed in 1976 and 1978.

In a model often referred to, the sources of S-bursts move outwards from Jupiter along the magnetic field lines within the Io flux tube<sup>4-6</sup>. The frequency of emission is close to the local electron gyrofrequency, while the frequency drift is determined by the longitudinal velocity component of the source. The  $D_E$ -effect can be explained by assuming that the emission is sharply beamed so that a relatively small change in  $D_E$  may lead to a selection of bursts having different drift rates and different emission angles.

A similar selection effect should also occur due to the variations in the CML and the geocentric phase of Io. According to the Earth-Jupiter viewing geometry<sup>7</sup>, the viewing angle of an Io-threaded field line varies as a function of the CML and Io phase more than it does as a function of  $D_E$ . The storm-averaged drift rates, however, show no significant dependence on the CML or Io phase. Thus the evidence suggests that the explanation of the  $D_E$ -effect based on sharp beaming from upward-drifting electrons in the Io flux tube is not correct.

Another possible interpretation is that the variation of drift rates is not determined by a selection process but that the rates of all bursts vary together. In that case, a true physical relationship with the Sun may be involved, such as the direction of arrival of the solar wind, related to the jovicentric declination of the Sun,  $D_S$  (ref. 8). Since  $D_S$  never differs much from  $D_E$ , this possibility cannot be ruled out on the basis of the present series of observations covering less than half a cycle of  $D_E$ .

**Fig. 3** Diagram as in Fig. 2, but for S-bursts observed in storms of region C.

One more possibility is that neither  $D_E$  nor  $D_S$  is the controlling factor, but that the solar activity is. If the storm-averaged drift rates are plotted as a function of the averaged sunspot number, an inverse relationship is displayed (not shown). This effect may be coincidental since the periods of  $D_E$  and of the solar activity are almost the same. Arguments relating to the relationships between  $D_E$  and  $D_S$  and the sunspot number have been presented previously in studies of the occurrence probability of L-burst and the longitude drift of emission regions<sup>8,9</sup>. Many years of observation would probably be necessary to show whether the true correlation is with  $D_E$  (or  $D_S$ ) or solar activity, or neither.

## Thermal conductivities of diamonds with absorption at 3.22 $\mu\text{m}$

MEASUREMENTS of the thermal conductivities of a hundred diamonds at temperatures between 320 and 450 K have been reported<sup>1</sup>. These results were interpreted in terms of nitrogen impurity alone, although it was suggested that hydrogen might give an effect in other diamonds with absorption peaks at 3.22  $\mu\text{m}$  wavelength. We report here measurements of the thermal conductivities of 24 natural diamonds with this IR absorption<sup>2,3</sup>.

A variety of phonon scattering mechanisms determine the thermal conductivity of diamond as a function of temperature<sup>4-7</sup>. Phonon scattering at crystal boundaries and large defects is dominant at low temperatures, whereas point defects are mainly important above room temperature. The conductivity of type IIA diamonds is extremely high over a wide temperature range. In the IR, these diamonds generally show only the fundamental lattice absorption (which is less than 1  $\text{cm}^{-1}$  above 6.5  $\mu\text{m}$ ). Additional absorption bands in type I diamonds at 7.80 and 8.30-8.55  $\mu\text{m}$  have been attributed to

**Fig. 1** Thermal conductivity at 320 K against maximum absorption at 8.30-8.55  $\mu\text{m}$ .  $\circ$ , Results for diamonds with 3.22- $\mu\text{m}$  peaks. The line represents the mean result for type I diamonds without 3.22- $\mu\text{m}$  peaks. The mean result for type IIA diamonds without 3.22- $\mu\text{m}$  peaks is shown with error bars representing 1 s.d. at upper left. Mean results from ref. 1 (Fig. 5).

nitrogen<sup>8</sup>, which can be present in two forms in the diamond lattice<sup>9,10</sup>. For the hundred diamonds of ref. 1, it was found that the maximum absorption in the range 8.30-8.55  $\mu\text{m}$  can be used to predict the conductivity and it was concluded that nitrogen in concentrations higher than about  $5 \times 10^{-3}$  atm% gives detectable lowering of the conductivity.

The diamonds used in the present work were polished to rectangular bars free from cracks and inclusions at  $\times 20$  magnification. Experimental details of the measurements of thermal conductivity and IR absorption were reported previously<sup>1</sup>. Mean thermal conductivity values  $k$  at 320 and 450 K were derived from measurements of each diamond at these and intermediate temperatures by means of  $k \propto T^{-s}$ , where  $s$  is a constant for each diamond<sup>1</sup> (Table 1). The maximum absorption value in the range 8.30-8.55  $\mu\text{m}$  is denoted as  $a(\sim 8.4)$ . The value  $p(3.22)$  is the strength of a narrow absorption peak at this wavelength. It is defined as the peak absorption minus the fundamental lattice absorption (indicated by the trend of the absorption curve across the base of the peak). The 3.22- $\mu\text{m}$  peak occurs in combination with one at 7.12  $\mu\text{m}$ .

Diamonds 101-104 are type IIA diamonds with 3.22- $\mu\text{m}$  peaks. Such diamonds seem to be rare. Their conductivities were found to be about as high as those of type IIA diamonds without 3.22- $\mu\text{m}$  peaks. However, the 3.22- $\mu\text{m}$  peaks of diamonds 101-104 are rather small and the diamonds with larger peaks also show absorptions due to nitrogen. Analysis of the absorptions of type I diamonds 105-124 gave no correlation between the amount or ratio of the two nitrogen forms and  $p(3.22)$ . Therefore, and in view of the existence of diamonds 101-104, the nitrogen impurity level seems to be independent of the value of  $p(3.22)$ . Diamond 124 has the lowest conductivity and a very high value of  $a(\sim 8.4)$ . From these values and ref. 1 it can be inferred that this diamond contains a very high concentration of nitrogen ( $0.5 \pm 0.1$  atm%). This has been confirmed by nuclear activation analysis<sup>11</sup>.

The results for the 24 diamonds are compared with the mean results for diamonds without 3.22- $\mu\text{m}$  peaks in Fig. 1. Values tend to lie below the line derived previously<sup>1</sup>. An extra thermal resistivity

$$R(320) = \frac{1}{k(320)} - \frac{1}{k_L(320)} \quad (1)$$

has been calculated for each diamond. The subscript L refers to the line in Fig. 1 or, in the case of diamonds 101-104, to the value for type IIA diamonds. The results have been plotted

against  $p(3.22)$  in Fig. 2. It can be concluded that diamonds with large  $3.22\text{-}\mu\text{m}$  peaks have a small but non-zero extra thermal resistivity. The same conclusion was reached from the data for 450 K.

This extra thermal resistivity probably arises from phonon scattering at hydrogen point defects in the diamond lattice. The presence of hydrogen impurity in some diamonds is well established, concentrations as high as 1 atm% having been reported by Sellschop *et al.*<sup>12</sup> and by Hudson and Tsong<sup>13</sup>. However, only one of Hudson and Tsong's diamonds showed the  $3.22\text{-}\mu\text{m}$  absorption. Runciman and Carter<sup>3</sup> attributed the  $3.22$  and  $7.12\text{-}\mu\text{m}$  absorptions to stretching and bending vibrations of C—H bonds and estimated the hydrogen density at a

**Fig. 2** Extra thermal resistivity at 320 K against the strength of the peak at  $3.22\text{-}\mu\text{m}$ . The accuracies of the ordinates are about  $\pm 0.01\text{ cm K W}^{-1}$  and of the abscissae  $\pm 0.3\text{ cm}^{-1}$ .

much lower level (equivalent to  $0.006\text{ atm}\%$ ), a result which they stated was confirmed by a vacuum fusion experiment. Chrenko *et al.*<sup>2</sup> also assigned these absorptions to C—H vibrations, but did not estimate the hydrogen concentration.

We believe that the larger hydrogen concentrations ( $\sim 1\text{ atm}\%$ ) are most probably associated with relatively large impurity aggregates such as magma droplets<sup>14</sup> or micro-inclusions<sup>15</sup>. These would not lower the thermal conductivity significantly above room temperature. Following Runciman and Carter<sup>3</sup> it seems that the  $3.22\text{-}\mu\text{m}$  absorption is probably associated with overall hydrogen concentrations some 2 or 3 orders of magnitude lower. These would then be the hydrogen point defect concentrations responsible for the extra thermal resistivity. This would be consistent with an extension to hydrogen defects of the analytical treatment of phonon scattering in diamond worked out by Turk and Klemens<sup>6</sup> (as used for nitrogen by Berman and Martinez<sup>7</sup>). However, the assumptions in this extension of the theory are so great that we can draw no positive support from such consistency.

We conclude that there is a small extra thermal resistivity associated with the sharp  $3.22\text{-}\mu\text{m}$  IR absorption in diamond. Both phenomena could be due to a small amount of hydrogen ( $\leq 10^{-2}\text{ atm}\%$ ) in point defect form, but such causation has not been proved.

We thank J. P. F. Sellschop, H. J. Annegarn, C. Madiba and S. Shongwe for nuclear activation analysis of diamond 124.

## Clouds and the long-term stability of the Earth's atmosphere and climate

CLOUDS dominate the albedo of the Earth and hence have a vital role in the global radiation balance. They are one of the most important physical properties of the atmosphere but the most difficult to parameterise. The forecasting of short-term climatological excursions (weather) requires numerical integration of complex dynamical models. However, over longer time periods it may be possible to include cloud cover without resorting to explicit atmospheric dynamics. Here we suggest that over evolutionary time periods ( $10^8$ – $10^9$  yr) the Earth's percentage cloud cover has remained approximately constant. This is in general agreement with present ideas about the stability of the Earth's evolution<sup>1–3</sup>. Over medium-term climatological periods ( $10^4$ – $10^7$  yr) we have found that the position of large cloud masses may be directly related to the changing surface configuration, caused, for example, by continental drift. Global cloud cover fluctuates about a mean, which is near the present-day value and reinforces albedo changes caused by surface configuration; this could be highly significant for theories of climatic change.

The high reflectivity of clouds results in their dominance of the global albedo of the Earth even though they cover, on average, only about 50% of the surface area. Recently<sup>4,5</sup> it has been demonstrated that the reflectivity in the visible wavelengths is more important than the complementary increase in IR opacity. Thus changing cloud amount cannot be ignored as had been suggested<sup>6</sup>, but must be considered as important in both long- and short-term climatic simulations. Cloud amount can be assumed to be a function of both the surface temperature and the available atmospheric water vapour. Contrary to some evolutionary models of the Earth's atmosphere<sup>7</sup>, we have found that the average global cloud amount has probably varied very little throughout the lifetime of the Earth.

Any long-term climatological model of the Earth must be concerned with calculation of the surface temperature,  $T_s$ , as we have observational data (from the geological record) for this parameter. It is generally agreed that throughout most of the planet's history<sup>2,8</sup> the value of  $T_s$  has probably not varied significantly from that of the present day. Changes in the value of  $T_s$  may cause responses within the atmosphere–hydrosphere

**Table 1** Albedo values,  $A$ , calculated for varying cloud cover

Percentage cloud cover	Albedo (%)
50 (present day)	30.1
40	24.6
60	35.7

system which could in turn perturb the global climate further. Some climate theories have developed the theme of temperature evolution via cloud changes<sup>7</sup>, although more recently<sup>1,8</sup> the generally stable nature of the Earth's evolution and long-term climate has been emphasised. Here we examine the atmospheric response to changes in the global average surface temperature. As it seems that the albedo effect of cloud is of greater importance than the absorption in the IR wavelengths, it will be changes in the albedo via cloud changes which will lead to climate perturbations. Therefore we have used a computer model to calculate the Russel-Bond spherical albedo of the Earth. This model derives a value for the global albedo,  $A$ , by integrating the reflected intensity over all points of the Earth's surface, making allowance for variations in reflectivity and angle of incidence at each point. The model has been described in detail elsewhere<sup>9</sup> and has been shown to give results consistent with measured values for  $A$ . The numerical integration includes the reflection due to clouds and is more satisfactory than calculations<sup>4,6</sup> which simply derive the global albedo from

$$A = A_c \alpha_c + A_s(1 - \alpha_c) \quad (1)$$

where  $A_c$  and  $A_s$  are the average reflectivity values of cloud and surface and  $\alpha_c$  the fractional cloud cover. Our model allows the importance and amount of both cloud and surface configuration to be estimated. The results have been used in two complementary modes below.

The major global sensitivity to changes in the surface temperature could be expected to come via the cloud response. It has recently been calculated<sup>10</sup> that, contrary to the widely held view, increasing surface temperature leads to decreased cloud cover (as a percentage of the surface area covered). Sellers<sup>11</sup> has suggested that this decrease could be caused by the build-up of convective clouds rather than stratiform clouds (that is clouds with larger vertical extent but smaller horizontal area). Several complex general circulation models are producing this type of result<sup>6,12</sup>. Roads<sup>10</sup> suggests that the cloud amount will probably decrease by 1% per degree K increase in  $T_s$ . It is now possible to investigate the atmospheric response to changes in the surface temperature (within the ranges expected from the geological evidence).

We have considered very large changes in  $T_s$  ( $\pm 10$  K) (compare the glacial/interglacial change of approximately 5 K) to illustrate the stability even in extreme conditions, but the results hold for smaller temperature changes also. If  $T_s$  were to be increased from its present value of 288 K to 298 K the resulting increased convection would lead to a decrease in the cloud amount of  $\sim 10\%$  and hence to a lower value of  $A$ . The new value of  $A$  has been calculated from the computer model (see Table 1). The average atmospheric lapse rate can be estimated from the values of the surface temperature and the temperature at the tropopause. This tropopause temperature,  $T_{\text{TOP}}$ , is approximated by

$$T_{\text{TOP}} = 2^{-1/4} T_e \quad (2)$$

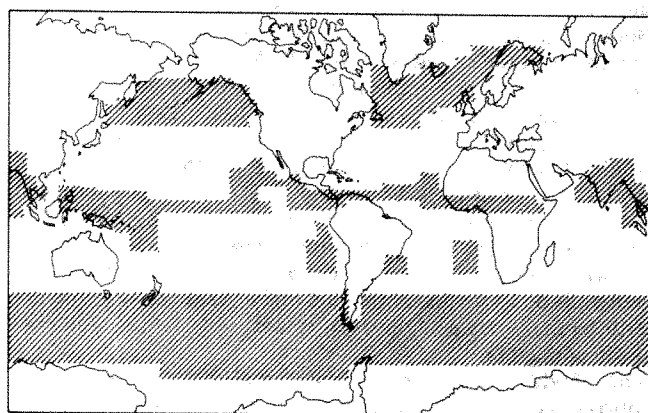

where  $T_e$  is the effective planetary temperature given by

$$\frac{S}{f}(1 - A) = \sigma T_e^4 \quad (3)$$

where  $\sigma$  is the Stefan-Boltzman constant,  $S$  the incident solar flux and  $f$  the planetary flux factor (which represents the ratio of the area of the planet emitting thermal radiation to the area intercepting solar radiation, and is a function of the planetary rotation rate and the absorption properties of the atmosphere<sup>8,13</sup>). Thus for the present-day situation we have  $T_s = 288$  K,  $T_{\text{TOP}} = 214$  K and the resulting lapse rate of between 6 and 7 K km<sup>-1</sup> (in good agreement with measured values and more complex models<sup>14</sup>).

In the surface temperature increase thesis the new value of  $T_{\text{TOP}}$  is 218 K, and thus the lapse rate increases which, in turn, is likely (on a global scale) to enhance cloud formation (negative feedback). Similarly  $T_s = 278$  K increases cloud, increases  $A$  to  $\sim 35.7\%$  (see Table 1) and gives  $T_{\text{TOP}} = 210$  K. The resulting lapse rate decrease would tend to inhibit further cloud build-up (of all types) and thus secure a return to a stable regime. Our contentions regarding the combined effect of changing the surface temperature and the atmospheric lapse rate are difficult to prove for the globally averaged situation we are discussing. However, similar arguments regarding the average atmospheric stability and the likelihood of cloud condensation have been considered for a number of planets by Goody and Walker<sup>15</sup>. Thus it appears that even large changes in  $T_s$  are unlikely to produce any catastrophic responses from the atmosphere.

The overall dynamic stability which is indicated by these results could, however, be disrupted by a secondary effect of changing cloud patterns via the possible variation in cloud positions. Obviously the cloud configuration on a global scale is a function of the general circulation. Within this framework the cloud cover may also be dependent on the predominant underlying surface type. Over very long time periods ( $10^6$ – $10^8$  yr) the relative positions of continents and oceans has changed greatly, and this may be an important factor for studies of the long-term temperature evolution. Henderson-Sellers and Meadows<sup>16</sup> have shown that continental land mass movements are of importance for albedo changes and hence may be responsible for enhancing or stimulating glacial periods. This preliminary study excluded cloud cover perturbations. The data regarding cloud distribution are still extremely sparse, and any attempt to draw comparisons between 'continental' and 'oceanic' coverage patterns at this stage must be tentative. Studies have been carried out, however, to estimate the likelihood of cloud cover of surface features for surveillance from satellites<sup>17</sup>. This study describes cloud cover in terms of climatological regions. I<sup>18</sup> have used this cloud data base to establish an objective method of cloud description using the beta probability distribution. From these studies it is possible to generate cloud probability maps (Fig. 1). These maps can show the areas most likely to be cloudy (or cloud free) over different time periods. In terms of the evolution of the global albedo certain features of Fig. 1 are particularly interesting.

**Fig. 1** Shaded regions have very high probabilities of cloud cover: July analysis (for details of analysis see ref. 18).

**Table 2** Global albedo values,  $A$ , calculated for the two extreme continental configurations examined

Clouds	Albedo (%)	
	Configuration 1	Configuration 2
No clouds	6.8	12.1
50% Cloud cover present-day distribution	30.9	29.0
50% Cloud cover extent of ITCZ reduced	29.9	—
50% Cloud cover extent of ITCZ increased	—	31.1

Configuration 1 has all the continental mass close to the equator while configuration 2 has the continents within 40° of the poles.

Note that the high cloud cover zones appear to follow the surface features (open ocean areas) as well as the general atmospheric circulation. Hence we suggest that over very long time periods the consequences of changing cloud configuration need to be assessed, in spite of the above conclusion that total cloud cover may have changed little. We have used the computer program to generate albedo values for the Earth, including both latitudinal changes in the positions of the continents and the predominantly cloudy regions. We have retained 50% cloud cover in these calculations, whilst slightly perturbing the areas of dominant cloudiness (Table 2). Both the magnitude and direction of the change in  $A$  are significant.

Note that global albedo values only are presented here. The interactions between solar radiation and the terrestrial climate are extremely complex and depend on many factors. This complex system has recently been considerably trivialised<sup>19</sup> by the suggestion that the current distribution of continental masses favours glaciation via the 'Milankovitch' orbital perturbation effect because of seasonality of temperatures (for example, the radiation distribution leading to cool northern summers and cold southern winters retaining and initiating ice cover respectively). This is contrary to the facts—climatological studies and more recent satellite data<sup>20</sup> immediately confirm that seasonal temperature change is greater in the Northern Hemisphere and that at present the Northern Hemisphere summer is warmer than the same season in the Southern Hemisphere. This is, of course, due to the global distribution of large oceanic areas and indicates that the 'Milankovitch' mechanism, if shown to be the cause of glacial epochs, operates despite the present global geography which opposes its effects in both hemispheres. Here we simply indicate the probable effect on the global radiation balance of cloud response to two extreme surface configurations.

The configurations chosen are: (1) all the land gathered closely around the equator; and (2) all the land areas within 40° of the poles. The albedo range in the absence of clouds is considerable<sup>16</sup>. However, imposition of present-day cloud reduces this difference to almost zero and reverses the ordering. We suggest from these studies that the global cloud cover could have responded to changes in the surface land/ocean configuration. We have therefore also calculated the likely global albedoes with a constant cloud cover percentage (50%) but with slight latitudinal changes in positioning of the predominantly cloudy areas. The change in  $A$  is considerable (7.2% for polar land masses, configuration 2). It is immediately clear that the postulated cloud changes re-establish the albedo difference between the two global configurations, the polar land mass case (configuration 2) still resulting in a higher value of  $A$  (although the difference between the two models is less than was previously anticipated<sup>16</sup>).

Our model calculations of the global albedo suggest two important conclusions. First, it seems that the average global cloud cover has remained approximately constant throughout the evolutionary history of the Earth's atmosphere. Second, a much smaller effect due to the reinforcement of surface forcing

of the albedo by perturbed cloud configuration is probably important in medium-term climatic change.

## Permo-Triassic and Jurassic <sup>40</sup>Ar-<sup>39</sup>Ar ages from Greek ophiolites and associated rocks

PRECISE radiometric dating of ophiolites and associated rocks is usually very difficult as the rocks are often altered by ocean floor metamorphism or during tectonic emplacement onto the continental margin. Only age determinations on primary mineral phases can be considered to approximate their initial crystallisation and cooling ages. The K-Ar technique is generally used to date ophiolitic rocks, but even if primary mineral phases are analysed, there is always the uncertainty that the resulting age could have been partially reset by later thermal or tectonic events. The <sup>40</sup>Ar-<sup>39</sup>Ar step heating method is able to detect and often to correct for any partial loss of argon, and thus overcome these problems. We have determined and report here <sup>40</sup>Ar-<sup>39</sup>Ar age spectra for hornblende separates from two unaltered samples of igneous rocks that are interpreted as the initial igneous products of rifting in the Othris region of central Greece. A third hornblende has been analysed from amphibolites believed to have been formed during tectonic emplacement of the Pindos ophiolite (Fig. 1). The ages suggest that the initial rifting began in Othris in the Permo-Triassic (~248 Myr), while tectonic emplacement of the Pindos ophiolite occurred in the middle Jurassic time (~180 Myr).

The breakup of a continental area in what is now the Othris region began in early Mesozoic time<sup>1</sup>. It is believed to be contemporaneous with the formation of picrites, wehrlites, dolerites, pillow lavas, tuffs and the deposition of associated cherts and dolomites assigned to the Agrilia Formation<sup>2</sup>. The age of the Agrilia formation is not well constrained. In parts of Othris the underlying Gavriani Formation contains Upper Permian and Lower Triassic fossils, but the Gavriani/Agrilia boundary may be diachronous<sup>2</sup>. Previously determined K-Ar ages on altered whole rocks<sup>3</sup> and amphibolite related to the emplacement of the ophiolites<sup>2</sup> were considered at best to be minimum ages of crystallisation (160, 185 Myr). <sup>40</sup>Ar-<sup>39</sup>Ar analyses of primary hornblende from a wehrlite and a dacite in the igneous sequence have been obtained (Tables 1 and 2). Age spectra and associated Ca/K ratios are given in Fig. 2a and b.

**Fig. 1** Published K-Ar ages with new  $^{40}\text{Ar}$ - $^{39}\text{Ar}$  data (underlined) on ophiolites and associated rocks in Yugoslavia, Greece and Crete<sup>2,13-15</sup>. Decay constants recommended in ref. 16 used for all data, with time scale in ref. 6.

Details of analytical procedure will be given elsewhere, but duplicate analyses indicate the precision of the data.

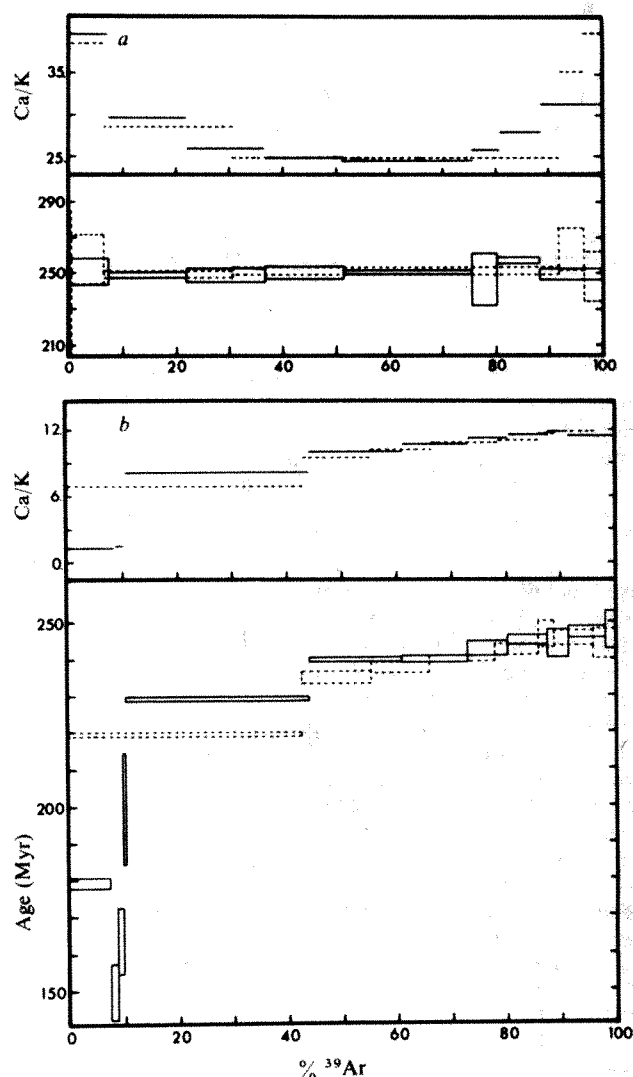

The wehrlite hornblende spectrum is flat (Fig. 2a) and indicates a crystallisation age of  $251 \pm 5$  Myr. In contrast, the dacite hornblende spectrum shows increasing age with increased

**Table 1** Sample locations and characteristics

Sample*	Locality	Description and probable significance
G-16R 108185	~2 km west of Andinita, Othris Mountains	Wehrlite: Olivine (Fo84.5) poikilitically enclosed by augite and minor brown hornblende. Part of a gabbro-peridotite cumulate sequence related to picrites. Inception of rifting and igneous activity.
G-18 108201	~3 km south-east of Dhomokos, Othris Mountains	Dacite: Phenocrysts of brown hornblende, biotite, albitised plagioclase showing relict zoning and minor quartz. The groundmass has recrystallised to fine-grained albite K-feldspar. Isolated outcrop in plain. Felsic member of the Triassic volcanic suite associated with rifting.
B76-24 123656	Avominsta valley, Perivoli	Amphibolite: Green hornblende showing strong lineation plus plagioclase. Associated with garnet-mica schists. Probably continental margin material metamorphosed by ophiolite emplacement.

\* Six-figure numbers from Harker catalogue, Department of Mineralogy and Petrology, Cambridge.

outgassing of  $^{39}\text{Ar}$  (Fig. 2b). This age spectrum approximates the diffusion loss pattern predicted by Turner<sup>4</sup> for later reheating and observed by Dallmeyer<sup>5</sup> in hornblendes in a remetamorphosed terrane. If it is assumed that the spectrum is the result of diffusive loss of the argon, then the crystallisation of the hornblende is approximated by the highest temperature step and indicates an age of  $245 \pm 5$  Myr or greater, similar to the wehrlite age. The minimum age observed in the low temperature steps suggests that the reheating took place at 150 Myr or later.

**Fig. 2** a, Age spectra for duplicate analyses of G-16 wehrlite hornblende. Integrated age is  $251 \pm 5$  Myr; 0.26% K. Error boxes ( $2\sigma$ ) in all figures are analytical only and do not include uncertainties in the irradiation parameter ( $\sim 1\%$ ). Errors on sample ages in the test and integrated ages do include this uncertainty. b, Age spectra for duplicate analyses of G-18 dacite hornblende. Integrated age is  $231 \pm 4$  Myr; 0.80% K.

These two ages of  $\sim 248$  Myr (near the Permo-Triassic boundary<sup>6</sup>) are the oldest ages so far determined on igneous rocks associated with initial rifting in central Greece. The ocean floor generated next to the continental margin cannot be older than these rocks, but it may be younger. Using the Red Sea as an analogy, Hynes<sup>1</sup> suggested that the initial igneous activity associated with rifting in the Othris region might precede truly oceanic rifting by as much as 40 Myr because of a slow rifting rate. However, Nisbet and Price<sup>7</sup>, on examining the cherts forming the upper member of the Agrilia Formation also

Fig. 3 Age spectra for B76-24 amphibolite hornblende. Integrated age is  $181 \pm 4$  Myr. Duplicate total fusion ages are  $186 \pm 6$  Myr and  $188 \pm 6$  Myr; 0.036% K.

suggested a slow rate of rifting ( $\sim 1 \text{ cm yr}^{-1}$ ), but they believed these cherts could have formed in an oceanic environment after only 7 Myr of rifting, resulting in an ocean basin 150 km wide. Thus a well-developed oceanic environment could have grown in a relatively short time period and the ocean floor could have an age indistinguishable within the error limits from the age of the early rifting volcanics (248 Myr). At present there are no biostratigraphic or radiometric data on the age of the ophiolites, but it is known that they were tectonically emplaced in Upper Jurassic or Lower Cretaceous time, about 135–145 Myr ago<sup>2,8</sup>. Most workers agree that not only the Othris ophiolites, but the Vourinos and Pindos ophiolites were probably emplaced at this time<sup>9,10</sup>, as well as some of the Yugoslavian examples<sup>11</sup>.

Amphibolites and other metamorphic rocks developed at the base of ophiolites are currently interpreted as having been created by the tectonic emplacement of a relatively thick and probably hot sheet of ophiolite over continental margin sequences<sup>12</sup>. Previously determined K–Ar ages on a hornblende separate and a whole-rock amphibolite from the rocks at the base of the Othris ophiolite gave average ages of 161 Myr. Because of the large analytical error ( $\pm 12$  Myr), the amphibolites did not appear significantly older than the emplacement age suggested by field evidence—about 135–145 Myr.

However, five K–Ar determinations on metamorphic rocks below three Yugoslavian ophiolites lying in the same zone as the Greek ophiolites (Fig. 1) also gave emplacement ages ranging from 160 to 171 Myr<sup>13,14</sup>.

We have analysed a hornblende separate (Fig. 3) from an amphibolite at the base of the Pindos ophiolite in northern Greece (Tables 1 and 2). Though initially emplaced in Mesozoic time, later Cenozoic thrusting has moved the ophiolite sheet so that it now lies tectonically on Eocene 'flysch'. This latest phase of emplacement has not reset the earlier Jurassic emplacement ages obtained from the amphibolites. The age spectra for 85% of the gas release is flat within the limits of analytical error and indicates an age of  $182 \pm 4$  Myr. The age clearly shows that the amphibolites have not been created by Cenozoic thrusting but are related to an earlier Jurassic period of emplacement. In Othris the ophiolite has not been moved again by Cenozoic thrusting, but the field evidence clearly indicates an Upper Jurassic or Lower Cretaceous emplacement. Thus the amphibolites in the Pindos and Othris ophiolites are significantly older than would be suspected from field evidence, but similar to radiometric emplacement ages reported from Othris and Yugoslavia<sup>2,13–15</sup>. We reconcile these data by postulating that the  $^{40}\text{Ar}$ – $^{39}\text{Ar}$  age represents the time when a hot ophiolite sheet over-rode sediments and/or basic igneous rocks on the lower continental slope, whereas the field evidence gives the age of final emplacement of the ophiolite onto a continental platform some 40 Myr later in the case of the Othris ophiolite and some 140 Myr later in the case of the Pindos ophiolite.

The most important conclusions from these data are that igneous activity associated with initial rifting in this western belt of ophiolites in Greece may date from the Permo–Triassic boundary, and that ophiolite emplacement began in the lower Jurassic. Whether emplacement was slow and steady or fast and episodic cannot be decided from the available information.

We thank our departments for support. The  $^{40}\text{Ar}$ – $^{39}\text{Ar}$  research is supported by NERC. We thank S. Barnes for collecting the specimen at the base of the Pindos ophiolite, and J. G. Spray and N. H. Woodcock for helpful comments, also J. G. Spray for his analysis of sample B76-24.

## Geological significance of a Middle Cambrian fauna from Antarctica

A NEW collection of a Cambrian fauna, occurring as erratics in a Quaternary moraine near Mount Provender (80°23'S, 29°55'W), western Shackleton Range (Fig. 1, inset) is reported here. It includes inarticulate brachiopods and trilobites, together with the first hyolithids and primitive molluscs from the area. Because of the isolation of the Shackleton Range, data on this fauna have accumulated only slowly<sup>1-4</sup>. It is important because it is located at a geographical extreme of the known extent of the Cambrian in Antarctica, and because it represents a contribution to our knowledge of world Cambrian faunas. Although the provenance of the fossiliferous erratics is problematical, it has important stratigraphical implications concerning the controversial age of the Blaiklock Glacier Group, for which ages as far apart as Cambro-Ordovician<sup>2,3</sup> and Permian<sup>1</sup> have been considered.

Other Cambrian faunas from Antarctica (Fig. 1) occur in the Transantarctic Mountains and in the Ellsworth Mountains of Lesser Antarctica. Like those of the Shackleton Range, they usually consist of assemblages of brachiopods and trilobites with or without associated archaeocyathids. In some instances exclusively archaeocyathid faunas have been found. The faunas range in age from late Lower Cambrian to Upper Cambrian<sup>5-9</sup>, although associated acritarchs at one locality in northern Victoria Land (Fig. 1, locality 9) suggest a possible brachiopod fauna might be as old as latest Precambrian<sup>10</sup>.

The Shackleton Range fauna occurs in fissile shales and siltstones. With the exception of the inarticulate brachiopods, which have shell material preserved, the fauna is present as internal and external moulds of moderate relief. In general, the brachiopods are preserved as unbroken but separated valves, the trilobites as disarticulated fragments, and the hyolithids as isolated conches. There are, however, moulds of completely articulated trilobite exoskeletons and broken brachiopod shell debris. The primitive molluscs are known from a single bedding plane on a small slab of shale; they are entire but laterally flattened.

All the brachiopods are identifiable with the obolids previously described from the area<sup>3</sup>. Two forms can be distinguished, one with thin smooth shells and the other with thicker shells having rows of concentric pits on the internal surfaces. Whether these represent two species or variants of the same species is uncertain.

The primitive mollusc is similar to some forms of *Helcionella* but is probably closer to *Mellopegma*<sup>11</sup>, a possible intermediate between the Monoplacophora and Rostroconcha. The specimens are small (the largest is 3.3 mm long), laterally compressed cap-shaped shells with strongly recurved apices and coarse concentric growth corrugations.

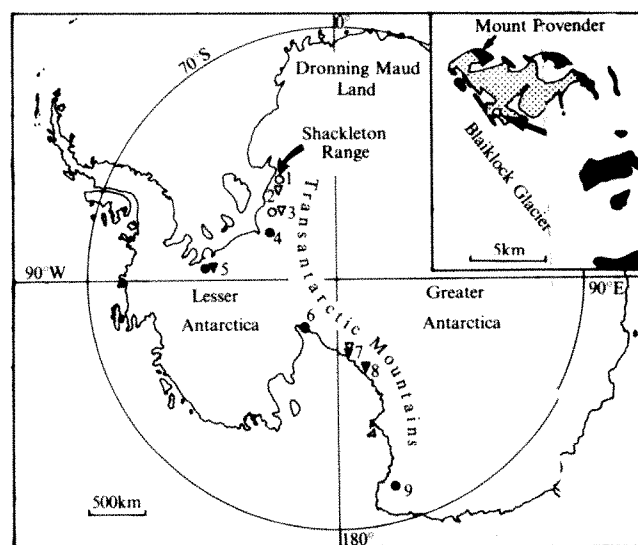

The trilobites include agnostids of *Triplagnostus* and *Peronopsis* types, and ptychoparids of *Ehmania*, *Lyraspis* and *Elrathina* types. As pointed out by Soloviev and Grikurov<sup>4</sup> these indicate a Middle Cambrian age for the fauna. The mollusc, if correctly assigned to *Mellopegma*, is also of stratigraphical value because its only previously reported occurrence is in the early Middle Cambrian of Australia. However, Runnegar and Jell<sup>11</sup> argued that morphologically similar forms must have existed as early as the Tommotian (early Cambrian).

Specimens in our collection suggest that, although the brachiopods and trilobites sometimes occur in mixed assemblages, they lived largely in different conditions. In general, the brachiopods occur in the siltstones or fine sandstones, whereas the trilobites occur more frequently in the shales. This, and the occurrence of fragmented shell accumulations, suggest that the brachiopods inhabited a slightly higher energy environment, periodically subjected to current action and reworking<sup>3</sup>.

The trilobite faunas of the Heritage, Neptune and Argentinia Ranges and Harold Byrd Mountains all occur in limestones, although associated Cambrian successions also contain clastic rocks. Together with occurrences of archaeocyathid limestones it seems that a belt of intermittent limestone deposition was present along the site of the Transantarctic Mountains in Cambrian times. By contrast, the trilobites of the Shackleton Range occur in non-calcareous shales and siltstones. In this respect they resemble the upper Middle Cambrian fauna of the Mariner Group, northern Victoria Land<sup>9</sup>, where trilobites are present in fissile mudstones attributed on sedimentological criteria to an open marine environment<sup>12</sup>. However, all known Antarctic Cambrian trilobite faunas are dominated by non-agnostids, a feature ascribed by Palmer<sup>13,14</sup> to faunas whose access to the open sea was restricted. Only the *Aphelaspis*-rich fauna of the Ellsworth Mountains<sup>8</sup> has apparently been interpreted as having had unrestricted access to the open sea<sup>13</sup>.

The source of the fossiliferous erratics is unknown but all previous geologists who have worked in the area have considered that they have not moved far. However, it is difficult to support the suggestion that the source underlies the Blaiklock Glacier Group<sup>4</sup>, presumably in pockets. Wherever the base of the Blaiklock Glacier Group is exposed it rests unconformably on the basement rocks and leaves no room for intervening sedimentary beds. Also, no evidence of the fossiliferous material, as derived blocks, has been found in the rudaceous rocks of the Blaiklock Glacier Group and the latter are obviously derived directly from the underlying basement rocks. Therefore, the original suggestion by Stephenson<sup>1</sup> that the source of the fossiliferous erratics may be intermediate strata of the group hidden beneath Blaiklock Glacier seems more probable and supposes a marine transgression following deposition of the lower terrestrial beds, and preceding rejuvenation of the landscape with subsequent deltaic sedimentation<sup>15</sup>.

Radiometric Rb-Sr age data on basement rocks in this area range from  $519 \pm 15$  Myr to  $656 \pm 66$  Myr (E. S. Grew and M. Halpern, unpublished). Compared with the Middle Cambrian

**Fig. 1** Distribution of Cambrian faunas in Antarctica. Circles denote shelly faunas, triangles denote archaeocyathid faunas (solid symbol = *in situ*, open symbol = moraine). 1, Mount Provender, Shackleton Range (Middle Cambrian); 2, Whichaway Nunataks (Lower Cambrian)<sup>5</sup>; 3, Argentina Range, Pensacola Mountains (Lower and Middle Cambrian)<sup>7</sup>; 4, Neptune Range, Pensacola Mountains (Middle Cambrian)<sup>7</sup>; 5, Heritage Range, Ellsworth Mountains (Upper Cambrian)<sup>8</sup>; 6, Harold Byrd Mountains (Middle Cambrian)<sup>6</sup>; 7, Beardmore Glacier area (Lower Cambrian)<sup>5</sup>; 8, Nimrod Glacier area (Lower Cambrian)<sup>5</sup>; 9, Evans Nève, northern Victoria Land (Lower and Upper Cambrian)<sup>9,10</sup>. The inset shows the Mount Provender area of the Shackleton Range and the collecting locality of the specimens discussed here (bold arrow). Solid areas are rock outcrop, stippled areas are moraine.

palaeontological age for the fossils, this indicates fairly rapid uplift and erosion to expose the grade of metamorphism immediately underlying the conglomerates at the base of the Blaiklock Glacier Group. These conglomerates are almost certainly the products of that uplift and erosion.

If the fossiliferous material is very local in origin it can be concluded from the limited evidence available that the lower part of the Blaiklock Glacier Group pre-dates the fossiliferous erratics so that it is no younger than Middle Cambrian. An upper age limit for the upper part of the Blaiklock Glacier Group of pre-late Carboniferous is indicated by a dolerite dyke, intruding an outlier of the upper (deltaic) part of the group at The Dragons Back, 25 km to the east<sup>2,15</sup>, which has a K-Ar age of  $297 \pm 12$  Myr (ref. 16).

The occurrence of a slab with rounded edges (about 1.5 m in diameter by 0.4 m thick) in the moraine with one surface covered in broken brachiopod shells (P. D. Marsh, personal communication) suggests a third possibility, that the fossiliferous slabs are disintegrated remnants of large glacial erratic blocks from a distant source. However, no other exotic erratics have been found in the moraine so that it is still more likely that the debris has not moved very far.

## Opisthopubic pelvis in the carnivorous dinosaurs

THE dinosaurs are subdivided into Saurischia and Ornithischia on the basis of their pelvic girdles<sup>1</sup>, which differ chiefly in the position of the pubis. In saurischians the pubis extends forward and downward whereas in ornithischians the supposed homologue of the pubis—the postpubis—is directed backward and downward parallel to the ischium. New finds from Mongolia, however, show that some carnivorous dinosaurs had a pubis orientated parallel to the ischium. As I report here, such a pubis has been found in the dromaeosaurids<sup>2</sup>, the segnosaurs<sup>3</sup> and a new genus from the Khara Khutul locality in

**Fig. 1** Pelves of the carnivorous dinosaurs. *a*, Pelvis in the Mongolian dromaeosaurids; the same in: *b*, segnosaurs; *c*, dinosaur from Khara Khutul; *d*, podokesaurids; *e*, saurornithomimids; *f*, oviraptorids; *g*, allosaurids; *h*, Mongolian tyrannosaurids; *i*, ornithomimids; *j*, American dromaeosaurids (*Deinonychus*) as reconstructed by Ostrom (the pubis seems to be incompletely turned back); *k*, *Archaeopteryx* as traditionally reconstructed from Berlin specimen; *l*, *Archaeopteryx* as reconstructed by Ostrom (the pubis seems to be incompletely turned back as well in *Deinonychus*). The drawings in *b*, *d*, *g*, *j*, *k* and *l* are taken from refs 3, 9, 14 and 16.

south-east Mongolia, which has not yet been described and possibly represents a new family.

Dromaeosauridae<sup>4-6</sup> are known from the Cretaceous of North America and Central Asia. In the Mongolian representatives of the family, *Velociraptor*<sup>5,7</sup> and two genera not yet described, the pubis is directed backward<sup>8</sup>. In the North American *Deinonychus*<sup>6</sup> the pelvis is not fully preserved and according to the most recent reconstruction<sup>9</sup>, the pubis seems to be incompletely turned back (Fig. 1*j*). The typical dromaeosaurid pelvis<sup>2</sup> (Fig. 1*a*) is characterised by a shallow ilium, a pubis with a broadly oval and laterally flattened distal end and an ischium significantly shorter than the pubis, with a large obturator process. Thus the dromaeosaurid pelvis has the general characteristics of the small theropods and only the direction of the pubis distinguishes it from the saurischian pattern (Fig. 1*d-l*).

The ilia in the segnosaurs (Fig. 1*b*) are well separated from each other and extremely deep, with very large anterior wings strongly deflected outward. The dorsal edge of the very short posterior iliac wing has a large cubic projection. It is not clear whether this projection should be considered homologous to the antitrochanter of ornithischians or whether it represents a new structure. The re-orientated pubis has a laterally flattened, large distal end; the ischium is elongated, its obturator process being

placed more distally than in dromaeosaurids and some other small theropods.

The preserved bases of the ilia of the Khara Khutul specimen (Fig. 1c) clearly show that these were also broadly separated and had cubic projections as in the segnosaurids. However, the pubis with the boot-like distal end is quite distinct from that in segnosaurids. The obturator process is situated distally, narrow and firmly coalesced with the pubic shaft, just above the distal end of the latter. Besides some common characteristics, the pelvises of the segnosaurids and the Khara Khutul specimen each have distinguishing features.

Thus, alongside dinosaurs with a typical saurischian pelvis, lived others with a pelvis not strictly 'saurischian'. I propose to refer to the former as 'prepubic' and the latter as 'opisthopubic', although these terms have already been used to designate two main pelvic structures in saurischians and ornithischians, respectively<sup>10</sup>. The opisthopubic pelvis probably provides evidence of evolutionary changes in the function and effectiveness of several pelvico-femoral muscles<sup>11</sup>.

There is considerable similarity between the opisthopubic pelvis (particularly of the dromaeosaurids) and the primitive ornithischian<sup>12</sup> pelvis, reflecting to some extent the relationships of the two main types of pelvis and confirming the unity of the dinosaur stock<sup>13</sup>. On the other hand, the existence of the opisthopubic pelvis supports the idea that the parallel evolutionary lines of carnivorous dinosaurs<sup>2</sup> included some that transcended the limits of theropod evolution, within which predatory habits and full bipedalism<sup>14</sup> were most effectively realised on the basis of a prepubic pelvis. The opisthopubic pelvis was evidently associated with specific lines of theropod evolution<sup>11</sup>. Furthermore, the existence of this type of pelvis makes it more likely that *Archaeopteryx* had a posteriorly directed pubis<sup>15,16</sup>.

In general, the opisthopubic pelvis must have had many advantages and probably appeared several times during both the early evolution of the dinosaurs and the ancestry of birds.

## Effect of salivary glands on wound contraction in mice

ALTHOUGH there has been speculation about the healing powers of saliva, recent interest in the salivary glands has been concerned with the physiology of nerve growth factor and epidermal growth factor<sup>1–4</sup>. However, saliva also contains other biologically active substances such as kallikrein<sup>5,6</sup>, amylase<sup>7</sup>, lysozyme<sup>8</sup>, immunoglobulins<sup>9</sup> and renin<sup>10</sup>. Lysozyme is believed to enhance healing by suppressing infection<sup>11</sup>. The wound healing process can be divided into epithelialisation, contraction, collagen synthesis and scar remodelling<sup>12</sup>; the evidence presented here suggests that contraction is affected by the salivary glands.

**Fig. 1** Rate of subpannicular wound healing in normal mice caged separately or together (a), or after sialectomy (b, c). Results are expressed as mean % area  $\pm$  1 s.d. for five to six mice. a, Normal animals were caged either separately (■—■) or in groups (□---□). The healing rate was significantly faster with communal caging ( $\Delta$ ,  $P < 0.001$ ). b, Mice caged in groups but with prior sialectomy (SMG, SLG) (●—●) or sham sialectomy (□---□). The rate of healing in sham-treated animals was the same as in non-operated controls (Table 1bII), but was significantly faster than in sialectomised animals ( $\Delta$ ,  $P < 0.001$ ;  $\blacktriangleright$ ,  $P < 0.05$ ). c, Animals caged in groups with sialectomised (SMG, SLG) mice in the same box as sham-treated animals. In this situation no differences were found in healing rate ( $P < 0.001$ ).

**Table 1** The effect of various operative and non-operative procedures on the rate of wound healing

The wound areas were traced on to paper using a transparent plastic sheet; the paper was cut and then weighed on a Mettler H54 balance. The weight of the tracing taken 2 h after wounding was arbitrarily designated as 100, and all subsequent measurements were expressed as a percentage. All sheets of paper came from the same batch and were of uniform weight ( $12.5 \pm 0.03$  g) for their size of  $43.2 \text{ cm} \times 27.5 \text{ cm}$ . Measurements were made on alternate days up to 12 d when further accurate measurements were not possible. The results were compared using a *t*-test for the mean % area ( $\pm 1$  s.d.). Animals were housed in groups of four to six during the experiments except in groups *aI* and *bI*. Sialectomy, carried out 7 d before the skin wound, included the submaxillary glands (SMG) and sublingual (SLG) or parotid glands as indicated. Ligation of the submaxillary and sublingual gland ducts was carried out with intervals of 0, 4 or 7 d before wounding.

A  $1\text{-cm}^2$  skin wound was cut into the centre of the back in 110 female C57BL/6J mice aged 50–100 d. Both superficial and deep wounds were studied; the superficial wounds were made by excision of skin only and the deep wounds by excision of skin and panniculus carnosus muscle together. The wound was allowed to dry and retract for 2 h before initial measurement. At 48-h intervals after wounding, the animal was lightly anaesthetised with ether, and the wound area measured. Table 1 summarises the measurements made at 0–12 d in each group. Histological sections were prepared from six controls and seven sialectomised animals on alternate days up to 12 d. Paraffin sections were prepared with both haematoxylin and eosin or Gomori Trichrome.

In normal mice, healing rate of suprapannicular (Table 1*aI*, II) and subpannicular (Table 1*bI*, II) wounds were almost the same, the deeper subpannicular wounds showing a slightly faster rate of contraction during the first 48 h. Wound healing in normal mice varied with the caging method (Fig. 1*a*). When the animals were caged separately their wounds healed slowly, with

the formation of a thick eschar after several days. The mice attempted to lick their own wounds but this was prevented by the wound position in the centre of the back. When the animals were caged in groups of four to six, all the wounds underwent marked contraction within 1–4 d. The initial square wounds became stellate, similar to patterns described in rabbits<sup>13</sup> and guinea pigs<sup>14</sup> (Fig. 2). Communal grooming and wound licking were observed whenever animals were housed together, and therefore all subsequent experiments were carried out with grouped mice.

After removal of both the submaxillary and sublingual glands (SMG, SLG), the contraction rate was significantly slower than in sham-operated animals ( $P < 0.001$ ), despite wound licking (Fig. 1*b*). The delayed contraction was similar to that observed in normal animals caged alone, with little change during the first 4 d. The sham-sialectomised mice showed rapid wound contraction similar to non-operated controls ( $P > 0.05$ ).

When sialectomised (SMG, SLG) and sham-operated animals were caged together (Fig. 1*c*), permitting communal wound licking, the healing rates were not significantly different ( $P > 0.05$ ), with all animals showing obvious early wound contraction.

After removal of the submaxillary glands alone, contraction of wounds was slower than in sham-operated controls ( $P < 0.01$ , except day 12). However, contraction was even slower when both submaxillary and sublingual glands were removed ( $P < 0.05$ , except day 10). This result implied that the relatively small sublingual glands, as well as the large submaxillary glands, contained an active substance affecting wound contraction.

Following bilateral parotidectomy the healing rate of wounds approached that observed in sham-operated controls ( $P > 0.05$ , except day 4), with contraction macroscopically indistinguishable from that of controls. This suggested that the parotid glands had no significant role in the effect.

To examine the possibility that the healing effect may be mediated by both exocrine and endocrine routes, experiments with animals which had undergone gland-duct ligation were carried out (Fig. 3). Despite intervals of 0, 4 or 7 d between duct ligation and wounding, healing patterns were not significantly different ( $P > 0.2$ ), and therefore a composite group is shown. Healing was significantly slower than in either non-operated or sham-sialectomised controls ( $P < 0.001$ ), until day 8. When

**Fig. 2** Effect of removal of submaxillary and sublingual glands on early wound shape. *Aa–c* Shows the rapid wound contraction seen in a normal animal at 0, 2 and 4 d, respectively. A wound of a sialectomised animal at 0, 2 and 4 d is shown in *Ba–c*. The wound outlines were traced from photographs, and are approximately  $\times 2$  actual size.

**Fig. 3** Effect of ligation of submaxillary and sublingual ducts on rate of suprapannicular wound healing. Results are expressed as mean % area  $\pm$  1 s.d. for 19 mice (only 12 mice on day 10). *t*-Test showed no statistical difference between the duct-ligated groups despite intervals of 0, 4 or 7 d before wounding, and therefore this figure shows pooled data (●—●). The sialectomised (SMG, SLG) (Table 1aIV) and sham-operated animals (Table 1aIII) are shown as 'ghosts' (---○) for comparison. Wound area was significantly smaller than after sialectomy (SMG, SLG) until day 8 ( $P < 0.05$ ), although it was also larger than in controls until day 8 ( $P < 0.0001$ ).

compared with sialectomised (SMG, SLG) animals, the wounds of the duct-ligated group were significantly smaller up to day 9 ( $P < 0.05$ ), suggesting that saliva was required for rapid wound contraction, and also the possibility of an early endocrine-mediated response. Even after sialectomy, epithelialisation was apparently normal on histological study, but the cause of delayed contraction was not determined.

The rate of wound contraction observed in this study is greater than that reported by other workers<sup>15</sup>, although animals have rarely been permitted or observed to lick their wounds<sup>16</sup>. We considered that the sialectomy wound might itself affect subsequent wound healing, although evidence of different healing rates between primary and secondary wounds is controversial<sup>13</sup>. However, as wounds in non-operated and sham-operated controls contracted equally fast, this possibility can be discounted.

The difference between wounded mice caged individually or in groups was the occurrence of communal wound licking, suggesting an effect either of licking itself or of a salivary gland factor. The mechanical action of the tongue, by minimising scab thickness, could reduce any splinting effect of the scab delaying wound contraction. The scab was certainly thinnest in communally licked controls (or sham-operated animals) with the fastest contraction, although this occurred in the first 2–4 d, before the scab became protuberant. The marginally faster healing in sialectomised animals caged together, compared with controls caged individually, suggested that there was a slight mechanical effect; however, any major effect was unlikely in view of the much slower healing observed in sialectomised animals licked by sialectomised companions than in controls similarly grouped.

Recent evidence suggests that contraction may be controlled by myofibroblasts within granulation tissue<sup>17</sup>. These modified fibroblasts contain smooth muscle-like contractile proteins as well as endoplasmic reticulum for collagen synthesis<sup>18</sup>. Contraction can be experimentally inhibited by smooth-muscle antagonists<sup>19</sup>, but there are no reported methods of its acceleration.

It is uncertain whether sialectomy (SMG, SLG) completely or only partially inhibited contraction; also, the mechanism by which contraction was affected is unknown. Vasoactive substances may accelerate the inflammatory response; kallikrein, which stimulates smooth muscle<sup>20</sup>, may also be involved

in myofibroblast contraction. Alternatively, an unrecognised salivary gland factor may facilitate fibroblast migration, or the differentiation of myofibroblasts, although the origin of these cells is still uncertain<sup>21</sup>.

These results suggest that the mouse submaxillary and sublingual salivary glands contain a factor(s), largely applied by licking, which accelerates early wound contraction. This may be of practical significance in human surgery, as wound contraction is believed to be similar in all mammals. The panniculus carnosus in animals merely allows faster contraction because of greater skin mobility<sup>12</sup>. The next step towards a practical use of our finding would be the isolation of the salivary gland healing factor postulated here.

## Normalisation of sister chromatid exchange frequencies in Bloom's syndrome by euploid cell hybridisation

BLOOM'S syndrome (BS) is a rare autosomal recessive genetic disorder characterised by stunted growth, Sun-sensitive telangiectatic erythema of the face and an abnormally high risk of cancer<sup>1</sup>. Cultured lymphocytes and fibroblasts from BS patients have a high frequency of spontaneous structural chromosome aberrations and characteristically high levels of sister chromatid exchanges (SCE)<sup>2</sup>. The primary defect at the molecular level is unknown, but the cytological findings are compatible with a deficiency in a DNA repair function<sup>3</sup>. The presence of a defect of DNA replication is also suggested by the demonstration that the rate of fork motion during replication in BS is slower than normal<sup>4</sup>. German *et al.*<sup>5</sup> have reported the coexistence of cells with both high and normal levels of SCE, suggesting that the defect in BS is regulatory. Tice *et al.*<sup>6</sup> concluded from co-cultivation experiments that SCE frequency is mediated by a diffusible agent(s) present in the medium of BS fibroblasts. Other investigators, however have shown suppression of SCE in conditions of co-cultivation<sup>7,8</sup>. We have clarified the conflict

between these results by examining euploid somatic cell hybrids between BS and normal human fibroblasts.

In the absence of selectable biochemical markers, we obtained hybrids by visual identification of tetraploid clones emerging from fusogen-treated cell mixtures<sup>9,10</sup>. Equal numbers of both parental cell types were co-cultivated for 36 h and then treated with a combination of polyethylene glycol and dimethyl sulphoxide (DMSO)<sup>11</sup>. After 10–12 days presumptive tetraploid colonies were located by phase contrast microscopy<sup>12</sup>, isolated and screened electrophoretically for heteropolymeric glucose-6-phosphate dehydrogenase (G6PD)<sup>13</sup>. Cytogenetically, hybrid clones were tetraploid with two Y chromosomes of different size and heterochromatin content. A reversion to normal levels of SCE in the BS parental phenotype (Fig. 1a and b) was noted in six independent hybrids isolated. Only three of these hybrid clones could be propagated sufficiently for subsequent quantitative analysis of the frequency of SCE. Additional metaphases were classified subjectively as 'low SCE' or 'high SCE', corresponding to the normal and the BS parental SCE phenotype, respectively. Results of these quantitative and qualitative analyses (Table 1) demonstrate that fusions of mutant (high frequency of SCE) with normal (low frequency of SCE) genomes result in complete correction of the mutant phenotype. In contrast, tetraploid clones resulting from fusion between BS parental cells retained the characteristic high frequency of SCE (Table 1).

The possibility that the observed normal low levels of SCE in the hybrids could arise from preferential fusion of the low SCE parent with a subset of BS cells which have low levels of SCE is unlikely for two reasons. First, there was no evidence for bimodality<sup>4</sup> within the BS fibroblast metaphases as regards levels of SCE: the parental BS cells uniformly showed characteristic high levels of SCE (Table 1). Second, in repeated collections, 20–25% of the BS parental metaphases included a small centric fragment derived from an apparently stable rearrangement involving acrocentric chromosomes. These cells were able to form complementing hybrids with normal cells, as observed in hybrid 24, which contained the centric fragment in all metaphases analysed. Thus, at least two karyotypically distinctive subsets of cells from this BS strain had SCE phenotypes which were recessive in hybrids with normal cells. In addition,

**Fig. 1** Cell cultures were grown in Waymouth media supplemented with 16% heat-inactivated FCS. The same lot of serum was used throughout the experiment to control for variation in levels of spontaneous SCE due to serum<sup>15</sup>. The BS strain (GM 1492; Human Genetic Mutant Cell Repository, Camden) was G6PD type B, had a variant size Y chromosome (q12; CBG40)<sup>16</sup> and had chromatid gaps, breaks and rearrangements in more than 16% of its metaphases in three subsequent collections. The G6PD type A strain was derived in our laboratory from neonatal foreskin. For analysis of SCE, cells were exposed to BUdR ( $3 \mu\text{g ml}^{-1}$ ) for 44 h in  $75\text{-cm}^2$  tissue culture flasks. Colcemid ( $0.04 \mu\text{g ml}^{-1}$ ) was added 2 h before collection and slides were prepared according to standard cytogenetic techniques. Differential staining of chromatids was accomplished with heat and Giemsa according to the method of Korenberg and Freedlander<sup>17</sup>. *a*, G6PD B type (BS) tetraploid metaphase, showing high SCE phenotype. *b*, hybrid metaphase with low SCE phenotype. Arrows point to the discordant Y chromosomes.

**Table 1** Quantitative and qualitative evaluation of SCE frequencies in parental, diploid, tetraploid and hybrid cultures

Cultures/Clone	G6PD type	No. of SCE per metaphase*	SCE phenotype	
			Low	High
BS parental				
diploid (GM 1492)	B	$75.4 \pm 8.9$ (22)	(0)	(150)†
Normal parental				
diploid (74–30)	A	$7.0 \pm 1.8$ (25)	(50)	(0)
Hybrids				
No. 6	AB	$12.4 \pm 2.7$ (15)	(17)	(0)

none of the hybrid clones seemed to display the characteristically high levels of unstable chromatid aberrations of BS cells in first division metaphases (defined by the staining response following incorporation of bromodeoxyuridine (BUdR)). The latter observations require quantification in a larger series of hybrids.

Our results do not support the evidence of Tice *et al.*<sup>6</sup>, which suggested that an endogenous production of a DNA-damaging agent caused the high frequency of SCE in BS cells. Rather, they are consistent with the idea that the high frequency of SCE reflects an intrinsic genetic defect in BS cells themselves.

Metaphases from BS heterozygotes show normal levels of SCE<sup>2</sup>. We plan to determine the level of SCE in hybrids between BS heterozygotes and related BS homozygotes. Such hybrids would contain three abnormal but only a single normal allele for the as yet unidentified gene defect. If such hybrids display intermediate levels of SCE, they would serve as a useful test system for heterozygosity<sup>14</sup>. Our technique of euploid–euploid hybridisation might, in addition, be used to investigate the question of genetic heterogeneity among BS patients<sup>1</sup>.

## Human brain tumour cell strains with deficient host-cell reactivation of *N*-methyl-*N'*-nitro-*N*-nitrosoguanidine-damaged adenovirus 5

HOST-CELL reactivation of a population of physically or chemically damaged viruses is said to occur when the plaque titre of the damaged (but not the control) virus population depends strongly on the cell strain selected to serve as the host to support virus growth<sup>1,2</sup>. Such cell strain-dependent differences in survival have classically been interpreted as reflecting known cellular differences in ability to repair DNA<sup>1,2</sup>. For example, we have previously demonstrated host-cell reactivation of UV-irradiated<sup>3</sup> or benzo(a)pyrene diol-epoxide I (anti)-treated<sup>4</sup> human adenoviruses. The survival of such treated virus populations is much greater when their plaque titre is measured using monolayers of fibroblasts with normal DNA repair than when using fibroblasts from patients having the genetic disease, xeroderma pigmentosum, which are deficient in repair of UV-damaged DNA. The work of Lytle and coworkers<sup>5,6</sup> and Day<sup>3</sup>, using human cells, has shown host-cell reactivation of UV-damaged viruses to occur only when nuclear replicating DNA viruses are studied. To assess the hypothesis that human tumorigenesis is often associated with repair-deficient cells, we undertook a study of host-cell reactivation of various kinds of damage using human cell strains prepared both from tumours of different organs and from skin of people having genetic predisposition to, or familial occurrence of, cancer. As part of this work, we measured the survival of adenovirus 5 treated *in vitro* with the carcinogen *N*-methyl-*N'*-nitro-*N*-nitrosoguanidine (MNNG). We found that the use of cells from 4 of 13 human brain tumour strains as viral hosts resulted in less survival of the MNNG-damaged viruses than did the use of more than 20 other cell strains prepared from human tumours or from unaffected human organs (Fig. 1, Table 1). Previous studies have not detected abnormal DNA repair in human tumours<sup>7</sup>. We believe this to be the first report of host-cell reactivation of MNNG damage by mammalian cells.

Data were obtained in eight experiments with A172 (Fig. 1, data from six) and in two each with A382, U-87MG and U-105MG. A172 was established from a glioblastoma<sup>8</sup> (a glioblastoma is a highly malignant (Grade IV) astrocytoma), the other three from astrocytomas<sup>8-10</sup>. Six other cell strains (T-98, 118MG, U-373MG, U-251MG, U-178MG and U-138MG) also established from glioblastomas or astrocytomas<sup>9,10</sup> showed approximately the same level of host-cell reactivation as the 23 remaining strains listed in Table 1 (data obtained using three of the six are included in Fig. 1). Among the strains showing normal reactivation of MNNG-damaged adenovirus 5 were three skin fibroblast strains prepared from patients having ataxia telangiectasia—AT3BI, AT5BI and AT81CTO (inactivation data for the first two of these is given in ref. 11). The colony forming ability of strain AT3BI has been found to be more sensitive to inactivation by MNNG than that of the KD, CRL1187, and CRL1220 normal strains<sup>12</sup>. One cell strain from a xeroderma pigmentosum patient, XP12BE, previously shown to be highly defective in host-cell reactivation of both UV-damaged<sup>3</sup> and benzo(a)pyrene diol-epoxide I (anti)-damaged<sup>4</sup> adenovirus 5, shows a normal level of host-cell reactivation of MNNG-damaged virus. Three skin fibroblast cell strains from persons with brain tumours, and belonging to cancer-prone families<sup>13-15</sup>, also show normal reactivation of the MNNG-damaged virus.

Although A172, U-87MG and U-105MG host cells reactivate MNNG-damaged adenovirus 5 poorly, Fig. 2 shows that they have normal host-cell reactivation of UV-irradiated viruses. The UV sensitivity of the virus reflected by the slope of the inactivation curve is experimentally indistinguishable from

that previously reported using 10 normal human skin fibroblast strains<sup>3</sup>. Thus the defective host-cell reactivation of MNNG-damaged adenovirus 5, characteristic of these strains, does not reflect a general decrease in their ability to support the growth of damaged adenoviruses. (While A172, U-87MG and U-105MG grow very well, the slow growth of A382 has slowed further experimentation, and UV survival was not tested with this strain.)

We interpret our results to mean that the A172, A382, U-87MG and U-105MG cell strains are defective in the ability to repair MNNG-damaged adenovirus 5. While we believe the MNNG lesion, which is not repaired well by these strains, to be

**Fig. 1** Per cent remaining plaque forming ability of adenovirus 5 as a function of MNNG concentration present with the virus. Human adenovirus 5, purified as previously described<sup>4</sup>, was diluted 1:1000 in 0.3 M Tris, pH 9.0. Aliquots (0.1 ml) of ethanol stock solutions of appropriate concentrations of MNNG (Aldrich) were added to 0.9-ml portions of the diluted virus suspension. After 30 min incubation at 37 °C, 0.1 ml of 0.5 M *N*-acetyl-L-cysteine<sup>16</sup>, pH 7.2, was added to each treated virus sample to reduce the remaining MNNG and thereby to terminate the viral inactivation. After 5–15 min further incubation, samples were diluted 1:10 into basal medium Eagle's medium (BMEM) (Microbiological Associates) containing 1% fetal bovine serum (GIBCO) plus 50 U penicillin and 50 µg streptomycin per ml. Plaque assays were then carried out as described previously<sup>3,4,20</sup>. The strains used, followed by the respective number of adenovirus 5 plaque forming units per ml from the dilution of non-treated viruses into BMEM were: ▲, A382,  $11.4 \times 10^5$ ; ●, U-87MG,  $30.2 \times 10^4$ ; ■, U-373MG,  $50.8 \times 10^4$ ; ○, U-105MG,  $45.4 \times 10^5$ ; □, U-178MG,  $53 \times 10^4$ ; △, A172,  $36.3 \times 10^4$ ; ▼, H4,  $90.8 \times 10^4$ ; ▽, 118MG,  $92.4 \times 10^3$ ; ○, CRL 1187,  $16.2 \times 10^4$ ; and ■, HEK,  $13.5 \times 10^5$ . Several points are displaced for clarity. Further cell strain data are given in Table 1 legend.

Table 1 Cell strains used

Human tumour cell strains	Tumour of origin	Donor age, sex	Skin fibroblast cell strains	Characterisation	Donor age, sex
Reactivation deficient			Reactivation proficient		
A172	Glioblastoma (astrocytoma, grade IV)	53, M	CRL 1220	Apparently normal	15, M
A382	Astrocytoma	10, M	CRL 1187	Apparently normal	14, M
U-87MG	Astrocytoma, grade II	54, F	CRL 1224	Apparently normal	40, F
U-105MG	Astrocytoma, grade III	62, M	KD (CRL 1295)	From blood blister of lip	31, F
			WR001	Cockayne's syndrome	9, F
			XP12BE (CRL1223)	Xeroderma pigmentosum	7, F
			AT3BI	Ataxia telangiectasia	4, M
			AT5BI	Ataxia telangiectasia	?, M
			AT81CTO	Ataxia telangiectasia	<1, M
118MG	Glioblastoma vs. astrocytoma	50, M	AL1405	Acute myelogenous leukaemia	6, M
U-373-MG	Astrocytoma, grade III	61, M	AL639	Acute monomyelogenous leukaemia	—
U-251MG	Astrocytoma, grade I	75, M	AL377	Brain tumour prone family	19, M
U-178MG	Astrocytoma, grade II	56, M	AL2673	Brain tumour prone family	38, M
U-138MG	Glioblastoma	47, M	AL1899	Brain tumour prone family	35, M
T-98	Glioblastoma	61, M

A204	Rhabdomyosarcoma	1, F			
			Other cell strains		
			Reactivation proficient		
			HEK	Human embryonic kidney	—
				Per cent of remaining plaque forming ability	

Cell strains A172, A204, A382, A498 and A704<sup>8</sup>, 118MG, H4, Hs783T, Hs683, Hs703 and Hs775T were from Dr Walter Nelson-Rees and Jack Weaver, with support from the NCI/Viral Oncology program, under the auspices of the Office of Naval Research and the Regents of the University of California. Cell strains T-98, U-87MG, U-105MG, U-138MG, U-178MG, U-251MG and U-373MG were from Dr Jorgen Fogh, Sloan-Kettering. Strains designated by 'CRL' were from the American Type Culture Collection, Rockville. HEK cells were from GIBCO. Strains designated AL were supplied by Dr Anthony Lubiniecki, Meloy (AL377 is from case IV-7 in NIH Clinical Epidemiology Branch family 0068 (ref. 13), AL1899 is from case 3 in family 0272 (ref. 14), AL2673 is from case V-8 in family 0165 (ref. 15), and AL1405 from family 0827). AT3BI and AT5BI were from Dr Colin Arlett and AT81C10 was from Dr M. C. Paterson, Atomic Energy of Canada. Strain WR001 was the gift of Dr Peter Nissley, NCI, NIH. Strain XP12BE belongs to xeroderma pigmentosum complementation group A (ref. 21).

in the DNA of a damaged adenovirion, the identification of this lesion as being an MNNG altered viral protein remains a possibility, although there are no reports of successful cellular repair of damaged proteins.

Candidates for repairable lesions produced by MNNG in adenovirus DNA are methylated bases<sup>16</sup>, phosphotriesters<sup>17</sup> and *N*-nitrocyanamide reaction products<sup>18</sup>. In our experiments, we activated MNNG by low amounts (*pH* 9) of hydroxyl ion, a reaction which gives methyl diazonium hydroxide (which subsequently becomes a methylating agent) and *N*-nitrocyanamide anion<sup>16</sup>. We have found that another type of virus treatment (treatment of virus suspensions by reduction of MNNG using *N*-acetyl-L-cysteine<sup>16</sup>) which produces a strong methylating agent, but does not produce active *N*-nitrocyanamide anion<sup>16</sup>, does not result in viral inactivation. This, by elimination, suggests that the repairable lesion may be a DNA-*N*-nitrocyanamide reaction product. Further results suggesting the possible importance of the *N*-nitrocyanamide moiety come from comparative studies of the kinetics of viral inactivation using MNNG and its ethyl counterpart, ENNG. Although these two agents produce different amounts of alkylated bases and phosphotriesters relative to their total reaction<sup>17</sup> (MNNG gives more total reaction than ENNG), they give the same viral inactivation kinetics per mol using repair proficient cells (data not shown), suggesting that the viral inactivating lesion is due either to the *N*-nitrocyanamide group, common to the two agents, or to some alkylated base or phosphotriester made in quantities such that the biological effects of the two agents are equal.

The fact that the decreased survival of MNNG-treated virus is observed in four of ten cell strains prepared from human astrocytomas suggests four possibilities for the relationship of MNNG host-cell reactivation deficiency to the origin of the astrocytomas that gave rise to the A172, A382, U-87MG and U-105MG cell strains: (1) tumorigenesis leading to astrocytomas is often initiated in a group of cells which is normally

deficient in host-cell reactivation of MNNG-damaged adenovirus; (2) such tumorigenesis often generates host-cell reactivation deficient cells; (3) such tumorigenesis is initiated in a cell, which, by somatic mutation, has become host-cell reactivation deficient; and (4) a large proportion of astrocytomas

Fig. 2 Per cent remaining plaque forming ability of adenovirus 5 as a function of UV dose to the virus. Purified human adenovirus 5 was diluted 1:1,000 in PBS, UV-irradiated, and assayed for plaque forming ability<sup>3,4,20</sup>. The strains used, followed by the number of adenovirus 5 plaque forming units per ml PBS were: ●, U-87MG,  $18.0 \times 10^5$ ; ○, U-105MG,  $30.4 \times 10^5$ ; △, A172,  $84.7 \times 10^4$ ; ▼, H4,  $22.6 \times 10^6$ ; □, CRL 1187,  $29.9 \times 10^4$ ; and ■, HEK,  $21.6 \times 10^6$ . See Table 1 legend for further strain data.

arise in people who have a genetic defect manifested by impaired host-cell reactivation of MNNG-treated adenoviruses. If the last possibility were correct, the disease identified would be another of the genetic diseases in which defective cellular repair of damaged DNA is associated with carcinogenesis. The three diseases known to be of this type, xeroderma pigmentosum, ataxia telangiectasia and Fanconi's anaemia, are infrequently associated with brain tumours<sup>19</sup>.

We thank Drs Anthony Lubiniecki, Jorgen Fogh, Walter Nelson-Rees, Jack Weaver, Colin Arlett, Peter Nissley and Malcolm Paterson for supplying cell strains, Drs Robert Miller, William Blattner, Lubiniecki, Nick Scudiero, Larry Keefer, Mike Mattern and, in particular, Ken Kraemer for helpful discussions and suggestions, and Carol Dowling for her expert help with the manuscript.

## The role of platelet-activating factor in platelet aggregation

PLATELET aggregation is mediated by at least three distinct mechanisms<sup>1,2</sup>. The first involves the release of ADP and is inhibited by its conversion to ATP by the combination of creatine phosphate and creatine phosphokinase (CP/CPK). The second is mediated by metabolites of arachidonic acid, particularly thromboxane A<sub>2</sub> (TXA<sub>2</sub>), and is blocked by aspirin or indomethacin, inhibitors of the arachidonate cyclo-oxygenase pathway<sup>3</sup>. It has been postulated that a third mechanism must exist, as neither CP/CPK nor aspirin, alone or combined, can inhibit aggregation induced by high concentrations of thrombin or the calcium ionophore A23187 (refs 1, 2, 4). Antigenic challenge of IgE-sensitized basophils releases a platelet-activating factor (PAF), probably a 1-lysophosphatidylcholine<sup>5</sup>. PAF has a potent action on rabbit<sup>6,7</sup> and human<sup>8,9</sup> platelet aggregation and release which is independent of the cyclo-oxygenase arachidonate pathways<sup>6,10,11</sup>. We have also obtained PAF from A23187-stimulated rat peritoneal<sup>12</sup> and alveolar (J.B., B.

**Fig. 1** Separation by TLC of aggregating substances released during ionophore-induced platelet aggregation. The upper part of the figure shows the thin layer chromatogram obtained by running a 10-μl aliquot of the 100 μl of the chloroformic platelet lipid extract. Spots were revealed with iodine vapour. The 90 μl remaining was run in parallel and divided into 11 square zones. Aliquots of 1 μl of the eluate from each zone were added to 0.35 ml of rabbit washed platelets ( $5 \times 10^8$  platelets per ml) incubated for 15 s with (lower tracings) or without (upper tracings) 5 μM indomethacin. Two distinct areas were detected: eluates from zones 3 and 4 (left hand) induced aggregation which was unaffected by indomethacin and can thus be considered as cyclo-oxygenase independent. Eluate from zone 10 (right hand) induced aggregation which was completely blocked by indomethacin, indicating the presence of arachidonic acid. Vertical scale: % light transmission; horizontal scale: time in minutes.

Arnoux and D. Duval, in preparation) macrophages. Moreover, thrombin and ionophore-induced platelet aggregation and the accompanying stimulation of phospholipase A<sub>2</sub> (refs 13, 14) are inhibited by the phospholipase inhibitor bromophenacyl bromide (ref. 15 and B.B.V., F. Fouque and M.C., in preparation), suggesting that the third mechanism of platelet aggregation might involve a lipid mediator. These findings prompted us to investigate whether platelets can form and release PAF in experimental conditions in which the ADP and TXA<sub>2</sub> pathways are fully blocked. We report here that this is indeed the case, and suggest PAF as a likely candidate for mediating the 'third pathway' of platelet aggregation.

In 12 experiments, blood was collected in EDTA (2.5 mM) from the ear artery of rabbits, and platelet-rich plasma obtained by standard centrifugation procedures. Washed platelets were prepared according to the method of Ardlie *et al.*<sup>16</sup> modified as described elsewhere<sup>6</sup>. In two experiments human blood was collected on citric acid–citrate–dextrose (for 9 ml of blood, 1 ml of a solution made of 8 g citric acid monohydrate, 22 g citrate trisodium dihydrate and 22.3 g glucose per l of distilled water); platelets were washed by two centrifugations at 1,000g for 15 min on a cushion of erythrocytes and then separated by centrifugation at 90g for 15 min (modified by J.B. from ref. 17). Washed platelets from rabbits ( $5 \times 10^9$ ) and from humans ( $3 \times 10^9$ ) were suspended in 10 ml of Tyrode's solution containing 2.5 g l<sup>-1</sup> bovine serum albumin (fraction V, Armour) and buffered with Tris (Sigma), 0.01 M, at pH 7.4. Platelets were stirred at 37 °C with or without 2.5 μM A23187 (Lilly). In four experiments aspirin (Prolabo) and the CP/CPK enzymatic system were added to platelets 10 min before the ionophore. In every experiment, the concentrations used, 0.1 mM for aspirin and 31.25 μg ml<sup>-1</sup> and 15.25 μg ml<sup>-1</sup> for CP and CPK (Sigma), respectively, were able to block aggregation induced by 0.1 mM arachidonic acid and to convert 50 μM ADP after 1 min incubation.

Ten minutes after the addition of the ionophore the suspension was ultrasonicated for 30 s in a Branson ultrasonicator, and the pH was adjusted to 10.6 with NaOH. Incubates were stirred

**Table 1** Release of platelet-activating factor and arachidonic acid from rabbit and human platelets during A23187-induced aggregation

		Additions		
		None	A23187	A23187 Aspirin and CP/CPK
Rabbit	PAF	0	1,957 ± 1,147	1,797 ± 740
	AA	756 ± 576	1,197 ± 653	732 ± 282
Human	PAF	0; 0	625; 725	ND
	AA	0; 0	145; 130	ND

Washed platelets were incubated for 10 min with or without A23187, a combination of aspirin and CP/CPK having been added 10 min before the ionophore (see text). Numbers represent platelet-aggregating activities expressed in arbitrary units per ml of incubate, recovered after TLC. PAF, activities from zone 3, indomethacin resistant; arachidonic acid (AA), activities from zone 10, indomethacin sensitive. Results of rabbit experiments are the mean ± s.d. of 12 experiments on  $5 \times 10^8$  platelets per ml; those of humans are from two separate experiments using  $3 \times 10^8$  platelets per ml. Note that arachidonic acid was also released from platelets used as controls, probably due to damage during extraction. ND, not done.

for 1 h at room temperature and 1.5 volumes of absolute ethanol were then added. The mixture was evaporated overnight under a stream of air and the residue was extracted twice with 1 ml of chloroform. After evaporation the new residue was dissolved in 100 µl of chloroform. Samples were spotted on silica-gel TLC plates (Merck, 60F-254) which were developed with a chloroform/methanol/water mixture (70:35:7). The plates were divided into 11 squares of  $1.5 \times 1.5$  cm, and the gel from each square was scraped and eluted with 500 µl of 60% ethanol. Eluates, usually 1-µl aliquots, were assessed for their aggregating activity on rabbit washed platelets as described elsewhere<sup>6</sup>.

Platelet aggregation was induced by eluates from two main areas (Fig. 1): zones 3 and 4, which had an  $R_F$  of ~0.35, similar to that of hog leukocyte PAF<sup>12</sup>, and zone 10, with the  $R_F$  of standard arachidonic acid<sup>12</sup>. The aggregating activity recovered from zones 3 and 4 was unaffected when 5 µM indomethacin was added to platelets before challenge (Fig. 1). In contrast, the eluates from zone 10 were totally inactive in the presence of the cyclo-oxygenase inhibitor, indicating that the aggregation was due to arachidonic acid (Fig. 1). Activities of arachidonate and PAF were expressed in arbitrary units—1 unit induced an aggregation producing a 1% change in light transmission.

In these experiments, PAF activity with a range of 565–4,000 U ml<sup>-1</sup> was obtained. In five control experiments no PAF was found when platelets were processed without the addition of the aggregating agent (Table 1). Preincubation of platelets for 10 min with aspirin and CP/CPK before addition of the ionophore did not affect aggregation or the formation and release of PAF. Human platelets also formed PAF on stimulation with the ionophore, although in lower amounts, even considering the lower number of human platelets in the release experiments. The presence of Ca<sup>2+</sup> was an absolute requirement for the release of PAF, as 2 mM EDTA suppressed it completely.

PAF purified on TLC was totally inactivated by porcine pancreatic phospholipase A<sub>2</sub> (Boehringer)<sup>5</sup>, an enzyme which specifically hydrolyses the fatty acid in the 2 position of glycerophospholipids. Furthermore, in two experiments TLC-purified PAF from rabbit platelets exhibited a similar retention time to that of PAF from hog leukocytes, when re-chromatographed using high-pressure liquid chromatography (HPLC). Therefore, PAF obtained from rabbit platelets fulfilled the criteria necessary to differentiate it from other potential aggregating agents<sup>5,12</sup>: refractoriness to indomethacin and to CP/CPK, sensitivity to phospholipase A<sub>2</sub>, solubility in organic solvents and typical migration pattern on silicic acid TLC and HPLC. PAF from human platelets was also insensitive to indomethacin and CP/CPK, was fully destroyed by phospho-

lipase A<sub>2</sub> and exhibited the same migration pattern as PAF from rabbit platelets or hog leukocytes on TLC (not tested on HPLC).

In seven experiments, rabbit platelets were centrifuged for 10 min after ionophore-induced aggregation. Sonication and exposure to basic pH were omitted. The recovery of  $63 \pm 29\%$  of total PAF activity in the supernatants indicated that PAF was released by aggregating platelets into the extracellular medium. The overall release of PAF by the ionophore-stimulated platelets was very high. Indeed, the amount of PAF released from rabbit platelets was 10–50 times greater than that required to aggregate 100% of a physiological platelet concentration mimicked in an aggregometer tube. PAF released from platelets may thus induce aggregation and secretion of the majority of platelets in the immediate vicinity, a basic mechanism for the formation of the platelet plug during haemostasis.

Our data indicate the existence of a calcium-dependent platelet mechanism leading to the formation and release of PAF during aggregation. This release occurs equally well whether the ADP and TXA<sub>2</sub>-dependent mechanisms are activated or whether they are inhibited by a combination of aspirin and CP/CPK. This strongly suggests that PAF is the mediator of the putative third pathway of platelet aggregation.

## Sodium-dependent cysteine transport in human red blood cells

ADEQUATE membrane transport of L-cysteine is necessary for red blood cell (RBC) survival, as this amino acid is essential for glutathione (GSH) synthesis and thus cell protection against oxidative damage. Thus, in sheep a genetically controlled L-cysteine transport defect leads to a reduced intracellular GSH concentration and shortened cell lifespan<sup>1–4</sup>. Human RBCs do not have the same amino acid transport system as sheep red blood cells (SRBC)<sup>5</sup>, the principal component being a high capacity, medium affinity system with a specificity broadly directed towards large neutral amino acids, the L-system of Christensen<sup>6</sup>. L-cysteine and its analogue L-α-amino-n-butyrate are carried by the L-system in human RBCs, but with a low affinity<sup>7</sup>. Most experiments on amino acid transport in RBCs,

**Fig. 1** *a*, Time course of L-cysteine uptake by human RBCs in sodium (●) and choline medium (○). *b*, Concentration dependence of L-cysteine uptake by human RBCs in the presence (●) and absence of sodium (○). Freshly drawn human RBCs were washed three times in medium containing 150 mM NaCl or choline Cl, 15 mM Tris-HCl (pH 7.6 at 37°C) and 5 mM glucose. The buffy coat was discarded. L-cysteine uptake was measured at 37°C by mixing 0.15 ml prewarmed cell suspension (haematocrit approximately 20%) in the appropriate medium with 0.15 ml prewarmed Na or choline medium containing 20 mM dithiothreitol and 1–50 μM L-cysteine (including L-U-<sup>14</sup>C-cysteine (0.5 μCi μmol<sup>-1</sup>); Radiochemical Centre, Amersham, UK). Incubations were stopped at predetermined time intervals by the addition of 1 ml ice-cold magnesium chloride solution (107 mM Mg Cl<sub>2</sub>, 10 mM Tris-HCl, pH 7.6 at 4°C). Cells were rapidly washed four times in this medium using an Eppendorf microcentrifuge (10s, 15,000g). Finally the washed cell pellets were lysed with 0.5 ml 0.5% (v/v) Triton X-100 in water, and 0.5 ml 5% (w/v) trichloroacetic acid was added. The precipitate was removed by centrifugation, and radioactivity in the protein-free supernatants determined by β-scintillation counting with quench correction. The time course studies (*a*) were made at a final L-cysteine concentration of 10 μM. The insert curve in (*b*) is fitted as  $\Delta = 49.83S/(14.2 + S)$  where  $\Delta$  is the difference between Na and choline uptake rates (μmol per l cells per h) and  $S$  is the L-cysteine concentration (μM). All values are means of duplicate estimates.

particularly involving the L-system, have revealed substrate affinities with apparent  $K_m$  values in the millimolar range, much higher than the physiological plasma levels of most amino acids. We have now investigated L-cysteine uptake in human RBCs over the concentration range 1–50 μM, as human plasma levels are around 20 μM<sup>8,9</sup>. As the early work of Yunis and Arimura<sup>10</sup> has shown that glycine and L-alanine transport are partially Na-dependent, we have also investigated the effects of removing external Na on L-cysteine transport. We report here that human RBCs transport L-cysteine by a previously unidentified high affinity, low capacity, Na-dependent uptake mechanism. This system has a uniquely high affinity for its substrate and is the first Na-dependent transport mechanism to be kinetically characterised in mammalian erythrocytes. At physiological substrate

concentrations it accounts for approximately half of the L-cysteine uptake into the cell.

Figure 1*a* shows the time course of L-cysteine uptake (extracellular concentration 10 μM) in either Na or choline medium. Uptake in both cases was linear over the first 10 min of incubation, with the flux in choline medium threefold lower than in the presence of Na. Replacement of Na by other cations gave inhibitions of 61% choline replaced; 65% Mg replaced; 54% Li replaced and 41% K replaced, suggesting that the reduced uptake was a true Na-replacement response. Extended incubation of cells (2 h) in the presence of 10 μM L-cysteine resulted in label accumulating to 33.4 and 15.4 μmol/l cell water in Na and choline medium, respectively. Figure 1*b* presents the concentration dependence curve for the initial rate of L-cysteine uptake in either Na or choline medium. The flux in choline medium was linear, whereas the Na medium data were consistent with the addition of a saturable component obeying simple Michaelis-Menten kinetics with apparent  $K_m$  and  $V_{max}$  values of 14.2 μM and 49.8 μmol/l cells/h, respectively. Kinetic studies on three individuals gave apparent  $K_m$  and  $V_{max}$  values (mean ± s.e. (range)) of  $17.6 \pm 1.7$  (14.2–20.0) μM and  $53.9 \pm 10.2$  (38.5–73.3) μmol/l cells/h, respectively.

The possibility that white cell or platelet contamination of the RBC population was responsible for the Na-dependent L-cysteine uptake was eliminated by comparing Na-dependence before and after filtration to remove white cells and platelets<sup>11</sup>, when fluxes were unaffected. The presence of reticulocytes was monitored by brilliant cresyl blue staining<sup>12</sup>. Reticulocyte counts were in the range 0–1.4% for the three subjects used, and there was no correlation between fluxes and reticulocyte counts. The magnitude of L-cysteine uptake over extended time periods is an additional argument against this effect resulting from L-cysteine accumulation in a minor component of the total cell population. The fact that the label accumulated to a level three times greater inside the cells suggests a possible concentrative effect. However, intracellular L-cysteine metabolism may be considerable, and makes it impossible to directly relate isotope accumulation to free intracellular L-cysteine levels. Further experiments using L-alanine<sup>14</sup>, an amino acid which is not significantly metabolised in RBC, revealed a Na-dependent uptake, confirming the observations of Yunis and Arimura<sup>10</sup>, and L-alanine was found to be an effective inhibitor of Na-dependent L-cysteine uptake. Therefore, as these two amino acids seem to share the transport system, L-alanine may prove a more convenient substrate for characterising this system in more detail. Further experiments measuring Na-dependent alanine uptake in human RBCs separated according to density on a Percoll gradient<sup>15</sup> gave 56% Na-sensitive alanine uptake (alanine concentration 0.2 mM) in the young cell fraction, and 43% in the densest fraction, corresponding to the old cells.

Increasing intracellular Na using the nystatin method<sup>16</sup> from 14 to 95 mmol/l cell water, decreased the Na-dependent uptake by 50% (external Na 150 mM). Neither ouabain 1 mM nor furosemide 1 mM inhibited Na-dependent amino acid uptake. At an alanine concentration of 0.5 or 1 mM, it was also possible to demonstrate an amino acid-dependent Na uptake, the mean Na/alanine coupling ratio being  $1.15 \pm 0.06$  (ref. 4).

The present results suggest that normal human RBCs possess a high affinity, low capacity Na-dependent L-cysteine transport system. The kinetic parameters of this system relate well to free L-cysteine plasma levels<sup>8,9</sup>, and intracellular L-cysteine requirements for GSH biosynthesis derived from consideration of intracellular GSH turnover<sup>13</sup>. We therefore conclude that this transport system may represent a major pathway for L-cysteine entry into human RBCs *in vivo*.

We thank Dr E. M. Tucker for carrying out the reticulocyte counts. M.W.W. thanks the Nuffield Foundation for financial support.

## Ca-stimulated ATPase in brush border and basolateral membranes of rat duodenum with high affinity sites for Ca ions

THE small intestine plays an important part in the calcium homeostasis of the body, but the mechanism by which calcium is absorbed is poorly understood. In young rats, active calcium transport occurs primarily in the duodenum and is strongly dependent on the vitamin D status of the animal<sup>1,2</sup>. In brush border membranes (BBM) as well as in basolateral membranes (BLM) the presence of Ca<sup>2+</sup>-ATPase activity has been reported<sup>3–5</sup>. Moreover, a good correlation is found between Ca<sup>2+</sup>-ATPase activity and net calcium transport in different segments of rat small intestine<sup>6</sup>. These observations suggest a role for Ca<sup>2+</sup>-ATPase in calcium absorption. The electrochemical potential of Ca<sup>2+</sup> in intestinal cells suggests that Ca<sup>2+</sup> influx is passive, whereas extrusion of Ca<sup>2+</sup> must be active<sup>6</sup>. Inherent in a role for Ca<sup>2+</sup>-ATPase in calcium transport is the requirement that Ca<sup>2+</sup>-ATPase be stimulated by concentrations occurring in the cytosol ( $\leq 10^{-5}$  M). So far, Ca<sup>2+</sup>-ATPase activities in small intestine have been assayed in the presence of 2 to 40 mM Ca<sup>2+</sup> (refs 3–5). We report here that Ca<sup>2+</sup>-ATPases in BBM and BLM of rat duodenum have  $K_m$  values for Ca<sup>2+</sup> activation of 1.1 and 0.5  $\mu$ M respectively. Also Ca<sup>2+</sup>-ATPase activity below 5  $\mu$ M Ca<sup>2+</sup> is higher in BLM than in BBM fragments. This asymmetrical distribution of Ca<sup>2+</sup>-ATPase activity may provide a mechanism for net calcium transport from lumen to blood.

**Table 1** Ca<sup>2+</sup>-ATPase activities of BBM and BLM fragments at various Ca<sup>2+</sup> concentrations

[Ca <sup>2+</sup> ] ( $\mu$ M)	Specific activity/purification factor ( $\mu$ M Pi per h per mg protein)	
	BBM	BLM
0.5	0.043 $\pm$ 0.010	0.12 $\pm$ 0.02
1.0	0.091 $\pm$ 0.023	0.17 $\pm$ 0.01
5.0	0.23 $\pm$ 0.02	0.18 $\pm$ 0.04
100.0	1.28 $\pm$ 0.03	0.42 $\pm$ 0.13

Observed specific activities (mean  $\pm$  s.e.m.,  $n = 5$ ) were divided by the purification factors of the BBM or BLM respectively. The purification factor for (Na<sup>+</sup>K<sup>+</sup>)ATPase, a BLM marker is  $7.9 \pm 1.1$  ( $n = 5$ ), while for sucrase, a BBM marker is  $39.8 \pm 2.7$  ( $n = 5$ ). These purifications are comparable to previously published studies<sup>5,6</sup>.

**Fig. 1** Eadie-Hofstee plots of Ca<sup>2+</sup>-ATPase activity at various calcium concentrations. Enzymatic activity is expressed as percentage of maximal Ca<sup>2+</sup>-ATPase activity, for example 3.6 and 54.4  $\mu$ M Pi per h per mg protein for BLM and BBM respectively. Calcium concentrations are expressed in  $\mu$ M. The data have been fitted based on a general rate equation for a two-site transport model<sup>17</sup> by means of an iterative procedure (least-squares method). Extrapolated  $V_{max}$  values for the high affinity sites are 1.58 and 6.53  $\mu$ M Pi per h per mg protein in BLM and BBM respectively. These  $V_{max}$  values represent 45% and 12% of the total Ca<sup>2+</sup>-ATPase activity at 1 mM Ca in BLM and BBM fragments.  $K_m$  values for the high affinity sites are 0.5 and 1.1  $\mu$ M in BLM and BBM.  $K_m$  values for the low affinity sites are 50 and 70  $\mu$ M for BLM and BBM respectively.

BLM and BBM were isolated from the first 15 cm of the small intestine of male Wistar rats (140–160 g) using the method described by Mircheff and Wright<sup>5,7</sup>. Plasma membrane fractions were essentially free of mitochondria, as succinic dehydrogenase (SDH) activity was  $\leq 0.2\%$  of the initial activity. This is important as calcium inhibits ATP hydrolysis in fractions enriched in SDH activity<sup>5</sup>. Ca<sup>2+</sup>-ATPase was assayed as the difference between the rates of ATP hydrolysis in the presence and absence of calcium. The standard assay medium contained: 100 mM NaCl, 5 mM MgCl<sub>2</sub>, 3 mM ATP and 50 mM Tris-maleate buffer (pH 7.4). Graded amounts of calcium were added. Below 50  $\mu$ M Ca-EGTA buffers were used. Free Ca<sup>2+</sup> concentrations were calculated by using stability constants and equations given in the literature<sup>8,9</sup>. All solutions used in Ca<sup>2+</sup>-ATPase assays were prepared with water which had been distilled three times in the presence of EDTA. Ca<sup>2+</sup>-free controls contained 4 mM EGTA. Aliquots of 25  $\mu$ l BLM or BBM suspensions (5–15  $\mu$ g protein) were incubated at 25 °C in 0.5 ml assay medium. The reaction was stopped with 0.5 ml 10% trichloroacetic acid and inorganic phosphate was assayed as described elsewhere<sup>10</sup>. Protein, sucrase, (Na<sup>+</sup> + K<sup>+</sup>)ATPase and SDH were assayed as described previously<sup>5,7</sup>.

The kinetics of calcium stimulation were studied in the concentration range  $10^{-7}$  to  $10^{-4}$  M and the results are presented as Eadie-Hofstee plots in Fig. 1. The plots show that the Ca<sup>2+</sup>-ATPase of each plasma membrane fraction has two sites, one of high and one of low affinity for Ca<sup>2+</sup> ions. The  $K_m$  values for the high affinity sites are 0.5 and 1.1  $\mu$ M for BLM and BBM respectively. The  $K_m$  values are similar to those of Ca<sup>2+</sup>-ATPase in red cell membranes and sarcoplasmic reticulum<sup>11,12</sup>. The low affinity sites have  $K_m$  values of 50 and 70  $\mu$ M for BLM and BBM respectively. Optimal activity occurs at Ca concentrations of 0.1 to 0.2 mM and no further stimulation or inhibition is observed at up to 2 mM. As the intracellular Ca concentration is expected to be lower than 10  $\mu$ M, the high affinity sites are of physiological importance. The demonstration of these sites makes the Ca<sup>2+</sup>-ATPase of plasma membranes of rat duodenum a candidate for a calcium pumping mechanism, in analogy to red cell membrane and sarcoplasmic reticulum calcium pumps<sup>11,12</sup>.

In young rats, calcium is actively absorbed in the duodenum and the distribution of  $\text{Ca}^{2+}$ -ATPase activity among the brush border and the basolateral membranes may provide a mechanism for calcium transport<sup>6</sup>. As BBM and BLM are not purified to the same extent, a direct comparison of specific activities is not informative. Therefore, in Table 1 specific  $\text{Ca}^{2+}$ -ATPase activities in BBM and BLM are given after correction for their purification factors. The table shows that below  $5 \mu\text{M}$  there is excess  $\text{Ca}^{2+}$ -ATPase activity in basolateral membranes. As vitamin D alters the permeability of the brush border membrane to calcium<sup>13,14</sup>, an increase in  $\text{Ca}^{2+}$ -influx may result in excess  $\text{Ca}^{2+}$  extrusion across the basolateral membrane due to the excess  $\text{Ca}^{2+}$ -ATPase activity. In order to test this hypothesis, studies have to be done in which  $\text{Ca}^{2+}$  fluxes across BBM and BLM vesicles can be correlated with the amount of ATP hydrolysed by  $\text{Ca}^{2+}$ -ATPase. Unfortunately, resealed BBM vesicles are orientated right-side out with their calcium and ATP binding sides on the inside<sup>15</sup>. The currently available techniques for BLM isolation yield vesicles too leaky to permit ion transport studies<sup>16</sup>.

We thank Dr G. Borst-Pauwels for providing a computer program and M. D. de Jong for technical assistance.

## Vanadate blocks cyclic AMP-induced stimulation of sodium and water transport in amphibian epithelia

INTEREST in the biological effects of vanadium has grown particularly since Cantley *et al.*<sup>1</sup> identified vanadate as a potent inhibitor of  $(\text{Na}^+ + \text{K}^+)\text{ATPase}$  and Balfour *et al.*<sup>2</sup> reported its striking natriuretic and diuretic properties in the rat. Such findings prompted us to investigate the effects of vanadate on amphibian epithelia, a model widely used for studying, *in vitro*, the membrane transport of sodium and water<sup>3,4</sup>. We found a ouabain-like action of metavanadate on active sodium transport. In addition, we report here a new biological effect of this compound on living cells: the inhibition of cyclic AMP-induced stimulation of transepithelial water flow.

The inhibition of sodium transport was mainly studied in frog skin, but similar results were obtained in toad bladder. Short circuit current (SCC) was taken as a measure of net sodium flux<sup>4,5</sup>. Addition of sodium metavanadate,  $\text{NaVO}_3$ , with V in the

**Fig. 1** Side-specific action of  $\text{NaVO}_3$  on sodium transport across the ventral skin of the frog *R. ridibunda*. The membranes were mounted in double chambers of the Ussing type and bathed by normal Ringer solution on both sides. The two lines indicated by solid circles and open circles correspond to the SCC values of two adjacent segments of the same skin. Exposure of both segments to a  $\beta$ -adrenergic agonist (isoprenaline, IP,  $1 \mu\text{M}$ ) induced similar increments in SCC. Subsequent addition of  $\text{NaVO}_3$  to the inner solution resulted in a progressive, ouabain-like, dose-dependent fall in SCC; in contrast, addition of  $\text{NaVO}_3$  to the outer solution had no effect. The two skin segments were sensitive to amiloride ( $10^{-4} \text{ M}$ ), a specific blocker of the sodium entry sites of the outer surface of the epithelium; this indicates the sodium nature of the SCC in this epithelium.

+5 oxidised state, to the solution bathing the internal side of the epithelium, resulted in a dose-dependent decrease in SCC (data not shown). The degree of inhibition and its time course were very similar to those observed in the presence of ouabain or harmaline<sup>6</sup>, two well known inhibitors of the sodium pump. A similar fall in SCC was seen in skins with higher rates of sodium transport due to pre-exposure of the epithelium to natriuretic agents such as catecholamines (Fig. 1), neurohypophyseal hormones, cyclic AMP and theophylline. In addition, pre-exposure of the skins to  $\text{NaVO}_3$  ( $10^{-3} \text{ M}$ ), almost completely prevented the stimulation of SCC by any of the above agents (Table 1). Finally, vanadate was clearly demonstrated to act at only one side of the membrane by the lack of effect of this compound when added to the solution bathing the outer surface of the skin (Fig. 1).

An inhibition of the  $(\text{Na}^+ + \text{K}^+)\text{ATPase}$  of frog skin by  $\text{NaVO}_3$  is the simplest hypothesis to explain the changes in SCC described here<sup>3</sup>. The concentrations of vanadate required to reduce SCC were rather high, but the same applies to ouabain and harmaline, in this tissue<sup>6</sup>. Such relative refractoriness of the enzyme may be related to the presence of an endogenous, ouabain-like inhibitor of the sodium pump, as recently suggested<sup>7</sup>, and/or to an intracellular site of action of vanadate<sup>8</sup> and harmaline<sup>6</sup>.

As the inactivation of the sodium pump affects the last step of the transepithelial movement of sodium, other biological effects of vanadium could remain undisclosed, for example, an interaction between vanadate and the cyclic AMP system of the epithelial cell. We previously observed this type of situation while studying the effects of harmaline in amphibian skin<sup>6</sup>. Therefore, we looked for effects of  $\text{NaVO}_3$  on another transport system, that of water. The osmotic flow ( $J_{\text{H}_2\text{O}}$ ) across the bladder or the skin of toads, *Bufo marinus*, was monitored continuously by means of an automatic, volumetric technique<sup>6,9,10</sup>. Addition of  $\text{NaVO}_3$ , up to  $10^{-3} \text{ M}$ , to the internal medium, did not cause any marked change in  $J_{\text{H}_2\text{O}}$  although a transient but reproducible stimulation was often noted during the first 3 min, particularly in toad bladder. A conspicuous effect was seen, however, when the epithelia were subsequently challenged with a hydrosomotic agent, such as vasopressin, in toad bladder (Table 1) and vasopressin or isoprenaline in toad skin (data not shown).

The increase in  $J_{H_2O}$  induced by these agents was inhibited by vanadate in a dose-dependent manner at concentrations of  $10^{-5}$ – $10^{-3}$  M. Similar results were obtained with theophylline (Table 1). Taken together, these effects of vanadate on  $J_{H_2O}$  could be interpreted as evidence for an inactivation of adenylyl cyclase. If this were the case, one would expect no inhibition of the hydrosmotic effect of exogenous cyclic AMP by  $NaVO_3$  (ref. 3). The experimental results, however, revealed completely the opposite (Table 1). Vanadate also inhibited  $J_{H_2O}$  in epithelia previously exposed to a hydrosmotic agent and thus having a high rate of water flow before  $NaVO_3$  addition; interestingly, the fall in  $J_{H_2O}$  did not go beyond basal water flow (Fig. 2). Finally, as already seen with SCC, the vanadate effect on  $J_{H_2O}$  was side-specific; when added to the outer medium,  $NaVO_3$  did not affect either basal or stimulated  $J_{H_2O}$ .

The biological effects of vanadate on both sodium and water transport described here are relevant to recent physiological<sup>2,11</sup> and biochemical<sup>1,8,12–15</sup> observations made with vanadium. The effects on SCC are consistent with the natriuretic properties<sup>2</sup> and the inhibition of  $(Na^+ + K^+)ATPase$ <sup>1,8,12–14</sup> reported by others. The effects on  $J_{H_2O}$  do not seem to be directly related to the sodium pump inhibition. It has been found in this and other laboratories that ouabain has no appreciable effect on  $J_{H_2O}$  in toad bladder, despite near-maximal reductions of SCC<sup>16</sup>. On the other hand, an interaction between vanadate and the cyclic AMP system would easily explain the  $J_{H_2O}$  data shown in Fig. 2

**Fig. 2** Two examples of the effect of  $NaVO_3$  on cyclic AMP-induced stimulation of water transport ( $J_{H_2O}$ ) across the ventral skin of toads *B. marinus*. The hydrosmotic actions of both vasoressin, VP (upper half), and isoprenaline, IP (lower half), were almost completely blocked by  $NaVO_3$  added to the inner solution. The automatic technique used to record  $J_{H_2O}$  has been described elsewhere<sup>6,9</sup>. The solutions bathing the epithelium were: normal Ringer (inner surface) and Ringer diluted 10-fold (outer surface). Although vanadate inhibited both basal and stimulated SCC, this agent seems to block only the cyclic AMP-induced stimulation of  $J_{H_2O}$  but not basal  $J_{H_2O}$ .

**Table 1** Block by vanadate of stimulated SCC and water flow in amphibian epithelia

	a, SCC (frog skin) ( $\mu A \text{ cm}^{-2}$ )

a, Abdominal skins of frogs *Rana ridibunda* were challenged with different natriuretic agents. In each experiment two segments of the same skin were used, one of which had been pre-exposed to  $NaVO_3$  added to the internal solution. Values in the first and third columns correspond to SCC recordings before addition of the agent indicated on the left; values on second and fourth columns correspond to peak responses obtained after exposure to the same agent. b, A similar protocol was applied to quarter-bladders of toads *Bufo marinus* to determine the effect of vanadate on cyclic AMP-dependent stimulation of water flow ( $J_{H_2O}$ ). Values represent cumulative  $J_{H_2O}$  (for 60-min periods), before and after addition of the hydrosmotic agent indicated on the left. The first two columns show results using the control quarter-bladders, the last two, paired quarter-bladders exposed to vanadate. Similar results were obtained in toad skin. Only the skins were challenged with isoprenaline, as the urinary bladder lacks  $\beta$ -adrenergic receptors. All values are mean  $\pm$  s.e.m. The number of paired studies is indicated in parentheses. Statistical analysis was done by using the paired *t*-test. Significance of *P* values is indicated by NS (non-significant), \* $<0.001$ , † $<0.01$  and ‡ $<0.05$ . On exposure to  $NaVO_3$ , fractional increases in SCC and cumulative  $J_{H_2O}$  values were significantly different with respect to control values for all the natriuretic and hydrosmotic agents tested.

and Table 1. Without obviously excluding an effect of vanadate on adenylyl cyclase<sup>15</sup>, a site of action beyond cyclic AMP generation must be postulated to account for the inhibition of the effect of exogenous cyclic AMP. Two lines of evidence suggest that an ATPase linked to mechanochemical proteins might be such a target: (1) the involvement of microtubules and microfilaments in epithelial water transport<sup>17–19</sup> and (2) the inhibition of dynein-ATPase by vanadate<sup>20–22</sup>. Further work is needed to elucidate this mechanism, which possibly contributes to the huge diuresis observed in the rat. Overall, our results indicate that the amphibian epithelium is a useful model for distinguishing between the many biological actions of vanadium.

## Neuronal localisation of immunoreactive enkephalin and $\beta$ -endorphin in the earthworm

SINCE the report by Simantov *et al.*<sup>1</sup> invertebrates have been thought to lack endogenous opiates and opiate receptors. As we have previously observed peptidergic neurones containing immunoreactive pancreatic polypeptide or vasoactive intestinal peptide in the earthworm<sup>2</sup>, we decided to search for, and report here our finding of, nerves storing immunoreactive enkephalin or  $\beta$ -endorphin in this species.

Various segments of earthworms (*Lumbricus terrestris*) were cut and frozen in a propane-propylene mixture cooled to the temperature of liquid nitrogen. After freeze-drying the specimens were fixed in formaldehyde vapour at 80 °C and embedded in paraffin *in vacuo*. Sections, 5  $\mu$ m thick, were deparaffinised and used for the immunohistochemical demonstration of enkephalin or  $\beta$ -endorphin, using either the indirect immunofluorescence technique<sup>3</sup> or the PAP technique of Sternberger<sup>4</sup>. The enkephalin antiserum used was raised against synthetic Leu-enkephalin coupled to bovine serum albumin. The characteristics of this antiserum are described elsewhere<sup>5,6</sup>. The  $\beta$ -endorphin antiserum (Milab) was raised as follows. Synthetic human  $\beta$ -endorphin ( $\beta$ -lipotropin (61–91); Peninsula) was emulsified in Freund's complete adjuvant. It was injected intracutaneously at multiple sites in rabbits, at a dose of 100  $\mu$ g of  $\beta$ -endorphin per rabbit. Two booster injections of 20  $\mu$ g were given at 3-monthly intervals. The third booster injection of 100  $\mu$ g  $\beta$ -endorphin was given a further 3 months later, and sera

**Fig. 1** Cerebral ganglion of the earthworm. Circumpharyngeal connective to the right. *a*, Many Leu-enkephalin-immunoreactive nerves and cell bodies (PAP staining). Note the peripheral localisation of the cell bodies and the central localisation of the nerves.  $\times 300$ . *b*,  $\beta$ -Endorphin-immunoreactive nerves and cell bodies.  $\times 400$ .

**Fig. 2** Cross-section of the cerebral ganglion of the earthworm to show the distribution and relative frequency of enkephalin- and  $\beta$ -endorphin-immunoreactive nerves and cell bodies. Some of the nerves seem to reach the circumpharyngeal connectives. Transsected nerves are indicated by dots.

were collected 2 months after this. The specificity of the  $\beta$ -endorphin antiserum (diluted 1:10,000) was tested in a radioimmunoassay system. It did not cross-react ( $<0.1\%$ ) with  $\alpha$ -MSH (ACTH (1–13)),  $\beta$ -MSH ( $\beta$ -lipotropin (41–58)), Met-enkephalin ( $\beta$ -lipotropin (61–65)),  $\alpha$ -endorphin ( $\beta$ -lipotropin (61–76)),  $\gamma$ -endorphin ( $\beta$ -lipotropin (61–77)),  $\beta$ -lipotropin (60–65),  $\beta$ -lipotropin (39–45), ACTH (1–24), ACTH (34–39) or ACTH (4–11).

The enkephalin antiserum was used in a dilution of 1:40 (immunofluorescence) or 1:400 (PAP staining), and the  $\beta$ -endorphin antiserum in a dilution of 1:20 or 1:200, respectively. Controls included application of antiserum inactivated by addition of excess Leu-enkephalin or  $\beta$ -endorphin (Peninsula) (10  $\mu$ g per ml diluted antiserum). Many neuronal cell bodies of different sizes and nerve fibres displaying intense enkephalin immunoreactivity were found in the cerebral ganglion. Characteristically, the cell bodies were located in the periphery whereas the nerve fibres occurred in the central part (Figs 1*a*, 2). Immunoreactive nerves were numerous within the cerebral ganglion and extended into the circumpharyngeal connectives. Immunoreactive nerve cell bodies and a few nerves were occasionally found in the subpharyngeal ganglion and in the abdominal ganglia. Cell bodies displaying  $\beta$ -endorphin immunoreactivity had a distribution similar to that of the enkephalin immunoreactive ones. Generally, the  $\beta$ -endorphin cells seemed to be larger in size and much fewer in number (Figs 1*b*, 2). They were clearly distinct from the cell bodies containing immunoreactive enkephalin.  $\beta$ -Endorphin-immunoreactive nerves were scattered in the central part of the cerebral ganglion but were absent from the circumpharyngeal connectives. In the subpharyngeal ganglion and the abdominal ganglia immunoreactive cell bodies and nerves were rare.

The results obtained indicate that enkephalin and  $\beta$ -endorphin, or closely related peptides, exist in the neurones of the earthworm. Hence, this suggests that opiate receptors may also be found in this species. In view of the present findings the belief that endogenous opiates and opiate receptors do not exist in invertebrates may have to be reconsidered.

While this manuscript was being prepared Rémy and Dubois<sup>7</sup> described a few  $\alpha$ -endorphin-immunoreactive cell bodies in the subpharyngeal ganglion of the earthworm. They did not find  $\beta$ -endorphin immunoreactivity.

This work was supported by the Swedish Research Council (04X-4499). The enkephalin antiserum was from Dr K.-J. Chang, Wellcome.

## Thermal activation of the visual transduction mechanism in retinal rods

INVERTEBRATE photoreceptors show electrical changes which apparently result from isomerisation of single rhodopsin molecules by light or thermal energy<sup>1-3</sup>. Observation of corresponding phenomena in vertebrates has been prevented by intercellular electrical coupling, which averages membrane potential over many photoreceptors<sup>4-6</sup>. Recently, however, recordings of membrane current from individual rod outer segments have revealed responses to single photons<sup>7,8</sup>. Here we report that similar electrical events occasionally occur in darkness, perhaps because of thermal isomerisation of rhodopsin.

Membrane current was recorded from single rod outer segments in toad (*Bufo marinus*) retina using a method described previously<sup>9</sup>. Pieces of thoroughly dark-adapted retina were

**Fig. 1** *a*, Sample records of rod outer segment current in darkness (two upper traces, sequential records) and bright light (bottom trace). Arrows below traces indicate times at which current exceeded a criterion level 0.5 pA above the baseline; these times are taken as occurrences of discrete events, discussed in the text. Using this method a total of 82 events were counted over a period of 2,631 s. In light the photocurrent reached a saturating amplitude of 19 pA and no events were evident in the observation period of 1,106 s. Records were low-pass filtered at 5 Hz with a 6-pole filter. Temperature 22 °C. *b*, Cumulative distribution of intervals between successive events in the same cell shown in *a*. Circles are experimental points; curve drawn according to equation (1) in text with  $\tau = 32$  s,  $N = 81$ .

**Fig. 2** Comparison of power spectral densities of dark events and single photon response in a rod.  $\circ$ , Difference power spectrum of dark events obtained as spectrum of all dark sweeps minus spectrum of dark sweeps not containing events. Experimental spectra based on 43 sweeps, each 40.96 s long, digitised at 20-ms intervals after low-pass filtering at 15 Hz. Continuous spectrum calculated from the Fourier transform of equation (2) in the text, with  $\alpha = 1.33$  s<sup>-1</sup>. Vertical scaling of theoretical spectrum, chosen to give best fit to points, corresponds to a mean rate of 0.022 s<sup>-1</sup> assuming dark events had the same amplitude (1 pA) as this cell's single photon response. Event frequency determined by counting was 0.023 s<sup>-1</sup>. Temperature 21.6 °C. Inset, jagged curve is the average of 80 responses of the same cell to dim flashes delivering an average of 0.8 effectively absorbed photons per flash. Flash timing shown by arrow. Smooth curve is equation (2), with  $\alpha = 1.33$  s<sup>-1</sup>.

placed in a chamber containing oxygenated Ringer and viewed in a compound inverted microscope. Retinal isolation and subsequent procedures were carried out under infrared illumination with an IR/visible image converter. Under visual control the outer segment of a rod in one of the pieces of retina was drawn by gentle suction into the tip of a glass micropipette. A low-noise amplifier connected to the inside of the pipette gave an output voltage proportional to membrane current. This current signal, the output of a light stimulus monitor, and synchronising pulses were led to an FM tape recorder for later analysis in a PDP 11/34 computer. For 'dark' recordings the preparation was enclosed in a black box which attenuated the very dim light (low scotopic level for humans) in the experimental room by a factor of 10<sup>6</sup>. Heated or cooled water could be circulated through a jacket surrounding the central Ringer pool in the experimental chamber; temperatures were measured with a calibrated thermistor about 0.5 mm from the tip of the recording electrode.

Figure 1a shows records of outer segment current in darkness (upper traces) and bright light (bottom trace). The noise in light was of instrumental origin, and the dominant component had a magnitude predicted by the measured value of the leakage resistance between electrode wall and outer segment membrane. The excess fluctuation in the dark records consisted of two components: (1) occasional discrete events (indicated by arrows below dark traces) of about 1 pA amplitude, and (2) a continuous small-amplitude fluctuation, not discussed further here. The discrete events resembled the average response to a single photon and in this cell were estimated to occur at a mean rate of 0.031 s<sup>-1</sup>. In the experimental conditions, however, the expected rate of photoisomerisations from stray light was at least two orders of magnitude below the observed event rate. This suggests that the events were not triggered by photons

but reflected spontaneous activation of the transduction mechanism.

If random independent excitations occurred in the rhodopsin molecules or intracellular disks of the outer segment the intervals between events should be exponentially distributed. Figure 1b compares an experimental interval histogram with this prediction. The continuous curve was drawn according to

$$n = N(1 - \exp(-T/\tau)) \quad (1)$$

where  $n$  is the number of intervals less than or equal to  $T$ ,  $\tau$  is the average interval, and  $N$  is the total number of intervals observed. The satisfactory agreement between experimental results and equation (1) supports the interpretation that the occurrence of events is a Poisson process describable by the single parameter,  $\tau$ , the average interval between events. Similar agreement between experimental results and theoretical curves was observed in seven other experiments, with a range of values for  $\tau$  of 76–17 s at temperatures of 15–26 °C.

The amplitude of the dark events was similar to the amplitude of the same cell's single photon response. To compare the kinetics of dark events and single photon responses we examined their power spectra; previous work<sup>8</sup> has shown that the current noise evoked by dim steady light has the spectrum of the average single photon response. The spectrum of the dark events was obtained as the spectrum of all dark sweeps minus the spectrum of dark sweeps not containing events. The average single photon response in each experiment was fitted by the relation<sup>9</sup> (Fig. 2 inset)

$$r(t) = k(\alpha t)^3 e^{-\alpha t} \quad (2)$$

where  $r$  is the photocurrent as a function of time  $t$  after photon absorption,  $k$  is a scaling constant and  $\alpha$  is a rate constant characteristic of the cell. This equation would apply if photoisomerisations cause electrical action by a process involving a series of four first-order delays<sup>10,11</sup>. The points in Fig. 2 are the spectrum of the dark events, and the curve is the calculated spectrum of the same cell's single photon response. Similarly close agreement between observed and calculated spectra was seen in experiments on eight other cells. The ability of the equation for the flash response to predict the spectrum of the dark events suggests that they are triggered by fluctuations at the input of the cascade. A simple explanation would be that the dark events result from a thermal configuration change in rhodopsin itself.

Figure 3 shows the temperature dependence of the rate of occurrence of dark events. The slope of the Arrhenius plot gives an activation energy  $E_a$  of 20.9 kcal mol<sup>-1</sup> for the thermal excitation process. In similar experiments on five cells the value of  $E_a$  was 23.2 ± 3.2 kcal mol<sup>-1</sup> (mean ± s.d.). The mean frequency of events in these experiments was 0.021 s<sup>-1</sup> at 20 °C.

**Fig. 3** Arrhenius plot of frequency of occurrence of dark events in a rod (log scale) against reciprocal absolute temperature. Detection of events in the continuous background noise was facilitated by digitally processing the current records with a 'matched filter' (ref. 15). In this procedure equation (2) was fitted to the rod's single photon response and then cross-correlated with the dark recordings. Vertical bars are based on the square root of the number of events counted. Slope of linear regression line corresponds to activation energy  $E_a$  of 20.9 kcal mol<sup>-1</sup>.

Assuming that the rod outer segment contains  $2 \times 10^9$  rhodopsin molecules and that thermal fluctuations in rhodopsin cause the dark events, the estimated rate constant for thermal excitation of rhodopsin is  $10^{-11}$  s<sup>-1</sup>. This corresponds to a molecular half life of the order of 1,000 yr. Additional parameters for the thermal excitation of rhodopsin at 20 °C were calculated as: Gibbs free energy of activation  $\Delta G^\ddagger = 31.9 \pm 0.13$  kcal mol<sup>-1</sup>, entropy of activation  $\Delta S^\ddagger = -31.7 \pm 11.2$  e.u.

Ashmore and Falk<sup>12</sup>, by analysis of membrane noise in neurones postsynaptic to dogfish rods, estimated values of rate constant and  $\Delta G^\ddagger$  similar to our own but found  $E_a$  to be 36 kcal mol<sup>-1</sup> and  $\Delta S^\ddagger$  to be +13 e.u. The differences may reflect different experimental methods. Chemical studies show that thermal isomerisation of 11-*cis* retinal in aqueous digitonin solution<sup>13</sup> is associated with a small negative activation entropy of -12.5 e.u. and  $E_a$  of 24.5 kcal mol<sup>-1</sup>, whereas for thermal denaturation of cattle rhodopsin in rod fragments Hubbard<sup>14</sup> found  $\Delta S^\ddagger = +214$  e.u. and  $E_a = 100$  kcal mol<sup>-1</sup>. Furthermore, extrapolation to 20 °C gives a rate constant for denaturation in rod fragments three orders of magnitude below the excitation rate constant derived here. Isomerisation is thus the more likely trigger of dark events. In a variety of solvents, however, derived rate constants for thermal isomerisation of 11-*cis* retinal alone are two to three orders of magnitude larger than the spontaneous excitation rate constant. This implies that linkage with opsin stabilises the 11-*cis* configuration of the chromophore.

## Photoinduced electron transport across phospholipid wall of liposome using methylene blue

PHOTOSENSITISED electron transport across membranes is a useful model reaction for photosynthesis. We have previously reported<sup>1</sup> the photoredox reaction in/on liposomes. Other similar studies have used chlorophyll as a sensitizer<sup>2,3</sup>, but this compound is easily broken and difficult to purify. The surfactant analogues of metal complexes (particularly tris-(2,2'-bipyridine) Ru<sup>2+</sup>)<sup>4–6</sup> are also widely used, but with such photosensitisers which possess long alkyl chains, electron transport does not occur in the absence of electron carriers such as quinones or carotenes. We report here the occurrence of photosensitised electron transport across the single phospholipid wall of the

**Fig. 1** *a*, Progressive spectral changes with time of irradiation; [MB] = 0.01 mM; [ASc] = 0.008 M. Numbers on each curve indicate the irradiation time (min)., UV spectra of each component in Tris buffer; (1) [MB] = 0.01 mM; (2) [ASc] = 0.008 M; (3) dispersed lecithin; (4) [potassium ferricyanide] = 4 mM; (5) 1 + 2 + 3 + 4.

liposome using methylene blue as both a sensitiser and an electron carrier. This is the first report of photosensitised electron transport across a membrane using a dye not only as a photosensitiser but also as an electron carrier.

The reaction was carried out in the single lamella liposome system. The liposome system, containing water-soluble electron acceptor ( $K_3Fe(CN)_6$ ) only in the inner aqueous phase of the vesicle and water-soluble electron donor (ascorbic acid) only in the outer aqueous phase, was prepared in the following way. Lecithin (isolated from egg-yolk<sup>7</sup>) was dispersed in 1 M  $K_3Fe(CN)_6$  solution buffered with 1 M Tris-Cl and 0.1 M KCl, pH 7.5. The dispersion was then ultrasonicated under  $N_2$  gas and the undispersed phospholipids were removed by gel filtration over a column of Sephadex G-50 equilibrated with the buffer solution. Then a given amount of methylene blue

**Fig. 2** Change in ferricyanide concentration with time of irradiation. O, [MB] = 0.008 mM, [ASH] = 8 mM; [ASH] > [ferricyanide]. ●, [MB] = 0.008 mM, [ASH] = 0.08 mM; [ASH] < [ferricyanide]. Arrow indicates the time at which the light was cut off.

was added. After being degassed by passing  $N_2$  gas, the dispersion was added to a solution of ascorbic acid at a final concentration of 8 mM. As soon as the solution was mixed, it was sealed in a Pyrex tube with a UV cell on the side arm (or sealed in a UV cell as a control). The photoreaction was carried out immediately by irradiating the solution with a super-high-pressure mercury lamp. Light of wavelengths shorter than 460 nm was completely removed by the use of a UV-46 filter.

In these conditions methylene blue was only very slightly reduced by ascorbic acid without light. However, when the light was irradiated, the absorbance at 420 nm decreased rapidly (Fig. 1*a*). Neither ascorbic acid nor methylene blue absorbs the light at 420 nm (Fig. 1*b*), and the absorption of lecithin was constant even with irradiation. Therefore, the decrease in the potassium ferricyanide concentration could be measured by measuring the decrease in the absorbance at 420 nm.

**Table 1** Relative reaction rates in different conditions

	Relative reaction rates	
	Irradiated	Non-irradiated
(A) Complete system	1	0.05
(B) A - ascorbic acid	0.01	0
(C) A - methylene blue	0	0

Complete system: methylene blue, 0.01 mM; ascorbic acid, 0.01 M.

Figure 2 shows the decrease in the ferricyanide concentration with time of irradiation. When the ascorbic acid concentration is higher than that of potassium ferricyanide, the reaction proceeds until all the ferricyanide is completely reduced. If the light is cut off, the reaction stops. When the ascorbic acid concentration is lower than that of potassium ferricyanide, the reaction stops after all ascorbic acid has been oxidised. These results confirm that ferricyanide is reduced.

As shown in Table 1, the reduction of  $K_3Fe(CN)_6$  did not occur in the absence of methylene blue or in the absence of ascorbic acid, even when the system was irradiated. The reaction was almost undetectable without light. This shows that either direct reduction of  $K_3Fe(CN)_6$  by ascorbic acid or the penetration of ascorbic acid did not occur. However, ascorbic acid cannot exist in the reduced form in the inner aqueous phase, and furthermore, the reduction rate increased with increase in the concentration of methylene blue.

From these results, the reaction can be summarised as proceeding through the following steps (see also Fig. 3).

where  $MB_0$  and  $MBH_0$  are methylene blue and reduced methylene blue in the outer aqueous phase,  $MB_i$  is methylene blue in the inner aqueous phase, AS and ASH are ascorbic acid and dehydroascorbic acid, and \* indicates an excited state.

We do not understand exactly how step (3) occurs, but it is clear that the electron is transported from ascorbic acid in the outer aqueous phase to  $K_3Fe(CN)_6$  in the inner aqueous phase, and that this electron transport is induced by the photo-irradiation. We are continuing our investigation of the transport process.

## Sequence divergence of rainbow trout protamine mRNAs; comparison of coding and non-coding nucleotide sequences in three protamine cDNA plasmids

SPERMATOGENESIS in the rainbow trout (*Salmo gairdnerii*) is associated with the onset of synthesis of the protamines<sup>1,2</sup>, a family of small, highly basic proteins consisting of 32 or 33 residues, of which approximately two-thirds are arginine<sup>3</sup>. By displacing the histones, the protamines have a unique role in packaging sperm DNA. The biosynthesis of the protamines has been studied in some detail, and polyadenylated protamine mRNA of about 290 nucleotides has been isolated from trout testis<sup>4,5</sup> and shown by *R<sub>0</sub>t* analysis to be made up of three to four components<sup>5,6</sup>. More recent work suggests that there are about six different protamine genes per haploid genome<sup>7</sup>. In contrast to the interspecific conservation of histone sequences, the observed rate of protamine sequence divergence between the closely related clupeid fishes such as trout, salmon and herring, is very high, and there is evidence that protamine genes have arisen following a doubling of the ancestral fish genome. Comparison of the cloned complementary DNA sequences and ultimately of the genes themselves will help to elucidate the molecular events involved in the evolution of these proteins. To study the chromosomal organisation of these genes and the control of their expression during spermatogenesis, I have constructed cDNA clones using purified poly(A)<sup>+</sup> mRNA as starting material. Here, the sequences of three of these recombinants are compared, revealing an unexpected pattern of divergence in the coding and non-coding regions, as well as a mutational 'hot-spot' corresponding to the major phosphorylation site of the protamines.

The sequences of the cloned cDNA fragments were determined by the methods of Maxam and Gilbert<sup>8</sup>. Figure 1 is a representative sequence ladder and Fig. 2 shows the extent of the cloned sequences aligned with reference to the functional chain terminator codon TAG. pTP4 contains a complete coding sequence, as well as 5'- and 3'-non-coding regions, and pTP8 and pTP11 have incomplete coding sequences; the fact that they both start at the same point may reflect some secondary structure of the parent mRNA. Both pTP4 and pTP8 contain the hexanucleotide corresponding to A<sub>2</sub>UA<sub>3</sub> which seems to be a general feature of eukaryotic poly(A)<sup>+</sup> mRNAs<sup>9</sup>; the presence of this hexanucleotide in protamine mRNA has been reported previously<sup>10</sup>.

The coding regions of the three clones were located by reference to the published amino acid sequences for rainbow trout protamines<sup>3</sup> (Fig. 3a, b). When these coding sequences are compared (Fig. 4) there is a striking homology between pTP8 and pTP11, with only one substitution in 80 nucleotides. The coding region of pTP4 is markedly different from that of the other two, and there is only a 78% homology when the

**Fig. 1** Poly(A)<sup>+</sup> mRNA was purified from pooled rainbow trout testes, double-stranded cDNA synthesised and inserted into the *Pst*I site of plasmid pBR322 using dG · dC homopolymer tailing, and transfected into the disabled host strain  $\chi$ 176 (ref. 5). Recombinants containing protamine cDNA sequences were identified by liquid hybridisation to cDNA synthesised from purified protamine mRNA<sup>5</sup>. Three recombinants, pTP4, pTP8 and pTP11, were chosen for sequence analysis. All work involving recombinant DNA was carried out in a Category II facility in accordance with GMAG recommendations. This figure shows a sequence gel of the 3'-non-coding region of pTP8. *Iap*I-cleaved pTP8 insert DNA was labelled at this cleavage site using T4 polymerase, and the unique end-labelled fragments separated on a 10% acrylamide gel and sequenced by the method of Maxam and Gilbert<sup>8</sup>. The gel shown is 12% acrylamide, 7M urea.

sequences are aligned, taking into account the putative deletion in pTP4. In contrast, a comparison of the non-coding regions of these cDNA fragments shows a complete reversal of these homology relationships (Fig. 3a). Thus, from the chain termination signal to the 3'-end of the segment of pTP11 which has been cloned, pTP8 and pTP11 differ by over 20% in nucleotide sequence; over this same region pTP4 and pTP11 are identical. This is unexpected because at least where it has been

**Fig. 2** The extent of the cloned cDNA fragments as determined from the sequence data. The cDNA fragments are aligned using the functional chain termination signal codon TAG (Fig. 3). Non-coding regions are shown as stippled and the polarity corresponds to that of the mRNA sequences. The cDNA fragments are flanked by dG·dC homopolymer linkers.

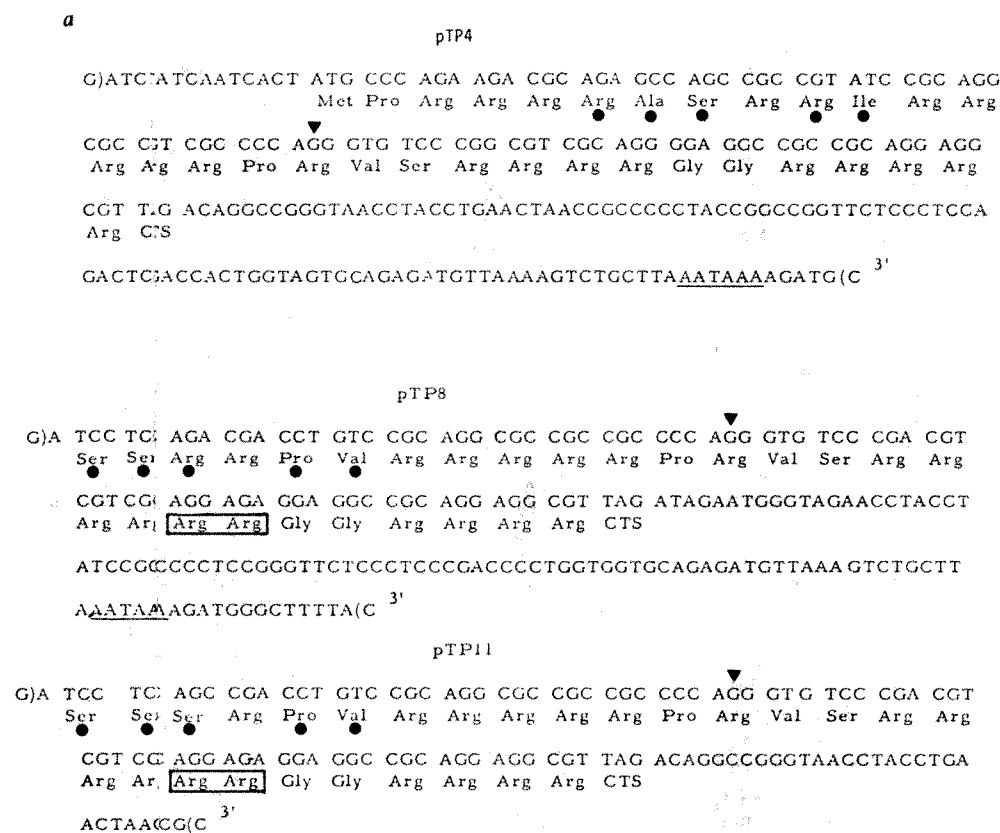

examined between species in globin mRNAs, coding regions are conserved whereas non-coding regions diverge more rapidly<sup>11-13</sup>. In the case of the intraspecific protamine clones both this pattern of divergence and its opposite occur.

Ohno and Atkin<sup>14</sup> have suggested a tetraploid origin of salmonid fishes, and evidence of extensive gene duplication is provided by studies of salmonid enzymes such as malate dehydrogenase<sup>15</sup> and glucose-6-phosphate dehydrogenase<sup>16</sup>. If the protamines have evolved from a gene duplication then since this event there has been strong selective pressure favouring conservation of the non-coding sequences in the genes cloned in pTP4 and pTP11, and the coding regions have been free to drift. Alternatively, the mRNAs may be the result of splicing events linking dissimilar coding regions to a common 3'-non-coding sequence. Both explanations could implicate the 3'-non-coding region in the coordinate control of protamine genes which may be expressed at different times during spermatogenesis<sup>17</sup>.

Within the 3'-non-coding regions of pTP4 and pTP8 the longest run of conserved sequence is one of 22 bases including the hexanucleotide AATAAA. Substantial homology has been found in this region between rabbit, human and mouse  $\beta$ -globin nucleotide sequences<sup>18,19</sup>, suggesting that these flanking sequences, as well as the AATAAA, may be involved in some common control function.

None of the predicted amino acid sequences corresponds exactly to any of those published<sup>3</sup> (Fig. 3a, b). One explanation for this is that the cloned sequences correspond to minor variants within the protamine population, as the mRNA was isolated from pooled testes. However, a more likely explanation is that some error occurred in the amino acid sequencing. The pattern of amino acid substitutions found in the predicted sequences suggests there is a mutational hot spot in residues 6-11 of the N-terminal region (where the N-terminal methionine residue of pTP4 = residue 1), as five out of six residues have changed in this region by base transition and sequence rearrangement. This hot spot is present to a lesser extent in the clupeines<sup>20,21</sup> but is not seen in the sequences reported by Ando and Watanabe<sup>3</sup>. It may be significant that this region contains three of the four serine residues phosphorylated by cyclic AMP-dependent protein kinase during histone displacement and nucleoprotamine assembly<sup>22,23</sup>.

The high frequency of arginine and serine in the protamines makes their mRNAs interesting for the study of codon usage. Davies *et al.*<sup>24</sup> reported that there is no preferential use of any arginine codon in protamine mRNA and that the dinucleotide CpG is under-represented, as in vertebrate DNA<sup>25</sup> and mRNA<sup>26</sup>, despite the fact that it is present in four of the six

**Fig. 3** Complete nucleotide sequences of the three protamine cDNA fragments carried in pTP4, pTP8 and pTP11, showing the encoded amino acid sequences. The cDNA fragments are flanked by dG·dC homopolymer linkers which are represented here by G)....(C'. CTS marks the functional chain termination signal. Amino acid differences between the cDNA encoded sequences are indicated by ●. Residues in pTP8 and pTP11 corresponding to the deletion in pTP4 are boxed. ▼ Indicates the positions at which there is a common difference between the cDNA encoded and the published sequences.

**Fig. 4** Composition of the shared nucleotide sequences of the protamine cDNA fragments carried in pTP4, pTP8 and pTP11. Coding sequences are separated from non-coding by /. Base transitions are represented by ●. Gaps in the sequence correspond to putative deletions required to give maximum alignment of sequences. Note that 29 nucleotides have been omitted from the 5'-end of pTP4.

possible arginine codons. The sequence data present a completely different picture. The arginine codons CGC and AGG are significantly over-represented, as is the serine codon TCC. CpG frequency in the coding regions of all three clones is that statistically expected from their G+C content and the dinucleotide appears exclusively in the arginine codon series CGX, which accounts for well over half the arginine codons in these sequences. However, in the 3'-non-coding regions, CpG frequency is depressed by about 50% compared to that expected. Methylation of DNA in eukaryotes seems to occur predominantly as 5-methyl CpG<sup>27</sup>, and it has been suggested<sup>12</sup> that this may be the reason the dinucleotide is under-represented, for in bacteria at least, 5-methyl C residues are mutational hot spots probably due to their spontaneous deamination to thymine<sup>28</sup>. The base transitions in these protamine cDNA fragments, however, fail to implicate CpG in sequence diversion, as there is only one instance of a C to T transition with G as its 3'-neighbour. C to T transitions in the first base of the arginine coding series CGX would generate the codons for cysteine and tryptophan or the chain terminator TGA. The presence of Cys and Trp in protamines could interfere with their function, thus selecting against C-T transitions in the DNA coding regions and it is significant that these amino acids are absent from both trout and the closely related herring protamines (clupeines)<sup>20,21</sup>.

This work was financed by SRC grant no. GR/A41397 to Dr Peter Butterworth. I thank Dr Beverly Griffin for providing space in her laboratory, Dr Ei-Ichi Soeda for helpful discussions, Dr Jeff Williams for help in preparing the manuscript and Dr Brigid Hogan for help and encouragement.

## Infectivity in mouse fibroblasts of polyoma DNA integrated into plasmid pBR322 or lambdoid phage DNA

THERE has been much speculation on the possible hazards of hybrid DNA technology<sup>1</sup>. An important question in this context is whether a viral DNA, covalently linked to a vector, can be transferred from within a bacterium into an animal cell, either *in vitro* or *in vivo*, and initiate viral infection. As a first step, it is necessary to determine whether a hybrid containing eukaryotic viral DNA can, on penetration into a permissive cell, give rise to virus formation, as is the case for hybrids containing a prokaryotic viral sequence<sup>2</sup>. As part of a risk-testing programme sponsored by EMBO, this question was investigated with mouse polyoma virus DNA. Polyoma virus will grow readily in mice; infection can be initiated by a single infectious particle as well as by naked viral DNA, and can be easily detected by monitoring the production of anti-viral antibodies. Virus production, and not tumour formation, was chosen as a criterion for biological activity because although polyoma virus will transform cells *in vitro*, tumours are produced *in vivo* only when large quantities of virus are inoculated into immunologically immature or immunosuppressed animals. We describe here the construction and characterisation of various plasmid pBR322 and phage  $\lambda$  derivatives containing polyoma DNA and their infectivity towards mouse fibroblast cells. The only recombinant molecules so far obtained which were infective as intact molecules were plasmids with dimeric polyoma DNA inserts.

Hybrid plasmid molecules were made with DNA from a readily identifiable mutant of polyoma<sup>3</sup> (which lacked an *Hha* restriction site) by digestion with restriction enzymes *Eco*RI or *Bam*HI, each of which cleaves at a single site, and ligation to appropriately cleaved pBR322. The molar ratios of viral to plasmid DNA used were between 2:1 and 1:1. *Escherichia coli* HB101 was transformed with the recombinant DNA, and colonies containing polyoma DNA were identified by *in situ* hybridisation<sup>4</sup> to <sup>32</sup>P-labelled polyoma RNA. Of 28 hybrid plasmids made by joining the constituent DNAs by their *Bam*HI sites, two had electrophoretic mobilities in agarose gels (0.5 and 0.52 relative to polyoma form I DNA) indicative of the presence of polyoma dimers. The remainder had higher relative mobilities (0.68-0.7) and were shown by analysis of restriction enzyme digests to contain one unit each of pBR322 DNA and polyoma, with both possible orientations being represented. The same type of analysis showed that the hybrid with a relative mobility of 0.5 comprised one molecule of pBR322 and two of polyoma DNA linked head-to-tail, whereas the hybrid with a relative mobility of 0.52 consisted of one molecule of pBR322 linked to a head-to-tail dimer of polyoma DNA with a deletion of about 800 base pairs. None of 48 hybrids of pBR322 and polyoma DNA joined through their *Eco*RI sites contained more than one molecule of polyoma DNA, but two contained two pBR322 molecules and both orientations of polyoma DNA with respect to pBR322 were found. Figures 1 and 2 show the analyses of

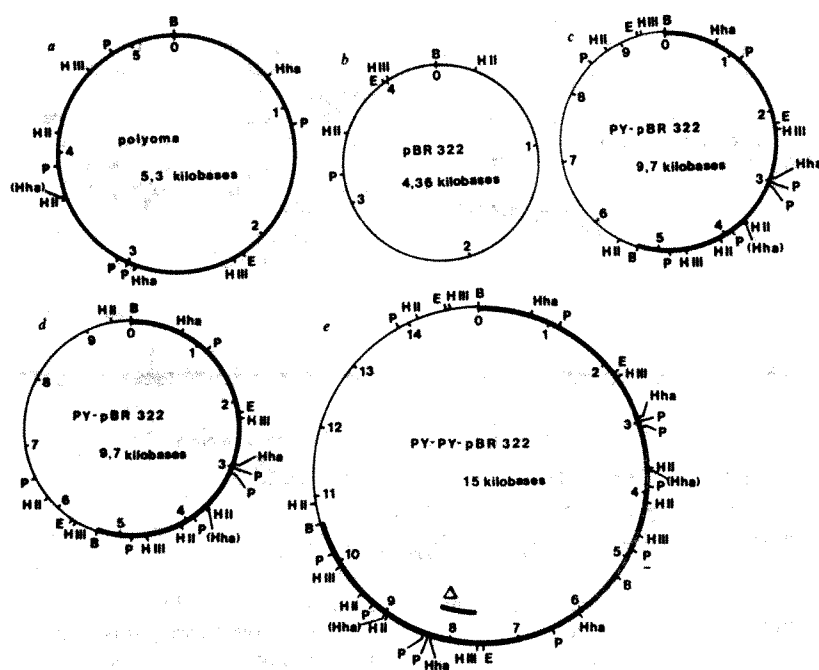

Fig. 1 Restriction maps of polyoma DNA, pBR322 DNA and some polyoma-pBR322 recombinant DNAs. *a*, Polyoma DNA (5,307 base pairs; from ref. 17). The DNA used here lacked the *HhaI* site (in parentheses) at position 26.4 from the *EcoRI* site. *b*, pBR322 DNA (4,361 base pairs; G. Sutcliffe and W. Gilbert, personal communication). *c*, Monomeric polyoma-pBR322 hybrid, joined at the *BamHI* sites so that the reading direction of the 'early' genes of polyoma and the *Tet* gene of pBR322 coincide (defined as head-to-tail). *EcoRI* cleavage should yield fragments of 7,075 and 2,575 base pairs. *d*, As *c*, except the reading directions are opposed (defined as head-to-head). *EcoRI* cleavage should yield fragments of 6,175 and 3,475 base pairs. *e*, Dimeric polyoma-pBR322 hybrid, joined at *BamHI* sites so that all units are head-to-tail, as defined above. Cleavage by *EcoRI* should yield fragments of 7,075, 5,300 and 2,575 base pairs. The other three possible combinations of orientations would yield the following *EcoRI* fragments: pBR322-Py (head-to-head)-Py (tail-to-head), 6,175, 5,300 and 3,475 base pairs; pBR322-Py (head-to-tail)-Py (head-to-head), 6,200, 6,175 and 2,575 base pairs; pBR322-Py (head-to-head)-Py (tail-to-tail), 7,075, 4,400 and 3,475 base pairs. B, *BamHI*; PstI; E, *EcoRI*; HII, *HindII*; Hh, *HhaI*.  $\Delta$ , site of deletion in hybrid D<sub>5</sub>.

some of these plasmids and their structures.

Polyoma DNA was also inserted into DNA from several bacteriophage  $\lambda$  derivatives, some of which could lysogenise their host, some which had temperature-sensitive repressors, and some which carried functional genes for phage-mediated recombination (*red*). Linear polyoma DNA, obtained by digestion with *EcoRI*, was ligated to the restricted vector DNA, and viable phage DNA molecules were recovered by *in vitro* packaging<sup>5</sup>. Recombinant phage were distinguished from parental ones on the basis of plaque morphology, or their inability to permit synthesis of  $\beta$ -galactosidase (as demonstrated by their failure to generate blue plaques on an appropriate plate) in their infected host<sup>6</sup>, or by plaque hybridisation with <sup>32</sup>P-labelled polyoma RNA<sup>7</sup>. Plaques of recombinants were picked and taken through at least two cycles of purification from individual plaques before preparation of stocks by lytic infection. DNA from purified phage was analysed by digestion with restriction enzymes and electrophoresis in agarose gels (Fig. 3), and by electron microscopy of heteroduplexes formed

with DNA from their parent vector, or another recombinant. All but one of the recombinants analysed contained a unit length insert of polyoma DNA and both orientations with respect to each vector were represented; the exception,  $\lambda$ -Py 48, contained less than a unit length of polyoma DNA, the deletion being located at one of the junctions between polyoma and vector. Some of the recombinants obtained are described in Fig. 4. Various approaches failed to yield any stable recombinants containing more than one molecule of polyoma DNA, although biological screening on the basis of restriction coefficient to *EcoRI* (ref. 8) and ability to plate on *pel*<sup>-</sup> (ref. 9) host strains indicated that several of the phage initially recovered contained dimers of polyoma DNA which were lost on further growth and purification. The reasons for this instability are unknown, but with the same vectors stable recombinants containing two molecules of pBR322 linked head-to-tail were obtained.

Recombinants were also made in  $\lambda$  derivatives with polyoma DNA cleaved at sites other than that for *EcoRI*. Partial digests of polyoma DNA with *HindIII* (for which it has two targets) were ligated with restricted DNA from two  $\lambda$  vectors<sup>6,22</sup> (Fig. 4)

Table 1 Infectivity of polyoma-pBR322 and polyoma- $\lambda$  hybrids

DNA preparation		Uncleaved DNA		Specific infectivity

## At Last! A Reliable Incubator Under \$100 Designed for Aerobic or Anaerobic Tissue Culture Experiments

Shown at ASM and  
FASLB Meetings

With this Modular Incubator Chamber you no longer have to worry about the inherent variability (due to CO<sub>2</sub>, temperature and humidity fluctuations) of present day continuous flow and anaerobic incubators. Simply place your experiment into the sealed chamber, purge the system with the required gas mixture and set in a controlled temperature environment.

Because each chamber is an isolated system you now have the flexibility to design experiments you previously thought were impractical or too expensive.

Chamber and tray components are made from rugged, non-toxic, uv resistant polycarbonate.

Multi purpose trays conveniently hold petri dishes, test tubes, T.C. flasks, microtest plates, etc.

Chambers can be stacked and interlocked for agitation or storage.

And now for the best part. The price of the chamber with 3 trays is only \$92. To order or for further information phone or write Billups-Rothernberg, Inc., Dept. N.E., P.O. Box 977, Del Mar, CA 92014 USA (714) 755-3309.

and again, two derivatives were used, one able to lysogenise its host and the other not. None of the recombinants isolated contained more than one molecule of polyoma DNA, but all contained the full monomer and with each vector three of the four possible derivatives were isolated (Fig. 4).

The infectivity of the polyoma-pBR322 hybrid DNAs before and after cleavage with the restriction enzyme used to generate the joined fragments was compared with that of polyoma virus DNA, using the DEAE method for transfection of mouse embryo cells<sup>10</sup>. Table 1 shows the specific infectivities of some of the polyoma-pBR322 hybrids joined through the *Bam*HI site. Hybrids containing one unit length of polyoma virus DNA gave less than 1 plaque-forming unit (PFU) per  $\mu$ g of hybrid DNA (less than 1 PFU per  $10^{11}$  DNA molecules), but cleavage of these hybrid DNAs with *Bam*HI resulted in a specific infectivity (in terms of unit lengths of polyoma DNA) similar to that of the viral DNA cleaved with *Bam*HI. Similar results were obtained with five of six hybrids that contained monomers of polyoma virus DNA joined to pBR322 through the *Eco*RI cleavage site

(results not shown). In no case was the uncleaved DNA infectious, but five of the hybrid DNAs were infectious after cleavage with *Eco*RI, which liberated a unit length linear viral genome. The reason for the lack of infectivity of the remaining hybrid after restriction remains uncertain; a non-infectious molecule may have been cloned, or infectivity of the polyoma DNA moiety may have been lost on passage of the hybrid in bacteria.

In contrast to the intact hybrids containing one unit of polyoma DNA, those containing 2 or 1.9 tandem head-to-tail genomes of polyoma virus DNA were infectious. The hybrid containing a dimer of polyoma virus DNA was 10% as infectious as intact form I viral DNA (in terms of PFUs per polyoma DNA molecule), whereas the hybrid containing 1.9 viral genomes was about 1% as infectious as viral DNA. The specific infectivity after cleavage with *Bam*HI of the two hybrids containing more than one unit of polyoma virus DNA was similar to that of similarly treated viral DNA in terms of PFUs per unit length of polyoma DNA molecules.

**Fig. 2** Restriction analysis of polyoma-pBR322 recombinant DNAs. Polyoma DNA (mutant, 0.5  $\mu$ g) and pBR322 DNA (0.5  $\mu$ g), both cleaved with *Bam*HI, were treated in 66 mM Tris-HCl (pH 7.5), 6.6 mM  $MgCl_2$ , 10 mM dithiothreitol and 1 mM ATP for 20 h at 0°C with sufficient T4 DNA ligase to cause about two-thirds of the linear DNA species to be polymerised, as judged by agarose-gel electrophoresis. *E. coli* HB101 was treated with  $CaCl_2$  and transformed essentially as described elsewhere<sup>15</sup>; 1,500 ampicillin-resistant colonies were obtained per  $\mu$ g pBR322. 430 colonies were transferred to a Millipore membrane, grown and assayed by the Grunstein-Hogness procedure<sup>4</sup>, using *in vitro* synthesised polyoma <sup>32</sup>P-RNA. Twenty-eight positive colonies were used to prepare 2-ml cultures, from which hybrid form I DNA was purified by a combination of published methods<sup>18,19</sup>. Formation and isolation of recombinant DNA using *Eco*RI-cleaved components was carried out in a similar way. For restriction analyses, DNA (1  $\mu$ g) was digested with the enzymes indicated and the products analysed by electrophoresis on agarose gels in the presence of ethidium bromide<sup>20</sup>. a, Native DNA samples: (1) pBR322 (the major band is form

I DNA, the minor bands are probably due to form II and to spontaneous pBR322 dimers, forms I and II). (2) Polyoma DNA; (3-8) hybrids linked through *Bam*HI sites: A<sub>2</sub>, D<sub>3</sub>, D<sub>5</sub>, D<sub>6</sub>, E<sub>8</sub>, G<sub>3</sub>. b, *Bam*HI cleavage. (1) pBR322; (2) polyoma; (3-8) hybrids linked through *Bam*HI sites: A<sub>2</sub>, D<sub>3</sub>, D<sub>5</sub>, D<sub>6</sub>, E<sub>8</sub>, G<sub>3</sub>; (9, 10) hybrids linked through *Eco*RI sites: A<sub>91</sub>, B<sub>46</sub>; M, marker:  $\phi$ 29 DNA incompletely digested with *Eco*RI. c, *Eco*RI cleavage. Lanes numbered as in b. d, Double digestion with *Pst*I and *Bam*HI. (1) Polyoma DNA; (2) pBR322; (3, 4) hybrids with more than one unit polyoma linked through *Bam*HI sites: D<sub>3</sub>, D<sub>5</sub>; (5) monomeric hybrid linked through *Eco*RI site: E<sub>8</sub>; M, marker: pCR1 DNA digested with *Bsp*II. e, Triple digestion with *Hind*II, *Hind*III and *Bam*HI. Lanes numbered as in d. One of the larger ('dimeric') hybrids (D<sub>3</sub>) gave two fragments on digestion with *Bam*HI: the longer one, which had the mobility of linear polyoma DNA, was present in about twice the molar yield (as estimated visually) of the shorter one, which had the mobility of linear pBR322. *Eco*RI cleavage of hybrid D<sub>3</sub> gave three products. The largest (7,100 base pairs) and the smallest (2,600 base pairs) of these had the same mobility as the *Eco*RI fragments of hybrids A<sub>2</sub> and G<sub>3</sub>, respectively, whereas the third fragment (5,300 base pairs) co-migrated with linear polyoma DNA. The hybrid D<sub>3</sub> therefore consists of one molecule of pBR322 and two of polyoma DNA linked head-to-tail, in the orientation shown in Fig. 1e. The other large (dimeric) hybrid D<sub>5</sub> gave three fragments on cleavage with *Bam*HI, one with the mobility of pBR322, one with the mobility of polyoma DNA, and one with a mobility corresponding to a chain length of about 4,700 base pairs. Thus, one of the polyoma DNA units has a deletion of about 600 base pairs. Digestion of D<sub>5</sub> with *Eco*RI yielded the same two smaller fragments (5,300 and 2,600 base pairs) as did the dimeric polyoma plasmid D<sub>3</sub>; however, the largest (7,100 base pair) fragment was replaced by a shorter one of about 6,400 base pairs (c). As shown in Fig. 1 legend, only the arrangement of Fig. 1e yields fragments of 5,300 and 2,600 base pairs; therefore, D<sub>5</sub> probably consists of one molecule of pBR322 linked to a head-to-tail polyoma dimer with a deletion of about 800 base pairs in the region yielding the large *Eco*RI fragment. The site of the deletion was located more precisely by analysing the products obtained after simultaneous digestion with *Bam*HI and *Pst*I on the one hand and with *Bam*HI, *Hind*II and *Hind*III on the other. The resulting fragments were compared with those from a similar digestion of polyoma DNA, pBR322 and the dimeric polyoma plasmid D<sub>3</sub>. As shown in d, hybrid D<sub>5</sub> doubly digested with *Bam*HI and *Pst*I, lacked a 1,850-base pair fragment specific to polyoma which was replaced by a shorter fragment of about 1,300 base pairs; after digestion with *Bam*HI, *Hind*II and *Hind*III one (of two) polyoma-specific fragments of 1,450 base pairs was replaced by one of ~700 base pairs. No pBR322-specific bands were missing. The deletion is thus located at the position indicated in Fig. 1e. The orientation of the A<sub>2</sub> and G<sub>3</sub> hybrids is indicated in Fig. 1c and the D<sub>6</sub> and E<sub>8</sub> hybrids in Fig. 1d.

Polyoma virus was isolated from several cell cultures that had been infected with the restricted plasmid containing monomeric polyoma DNA or with the unrestricted plasmid containing dimeric polyoma DNA; in all cases, the progeny had only the two *HhaI* sites characteristic of the mutant DNA used to produce the recombinant DNAs. To eliminate the possibility that free polyoma DNA (linear or circular) was present in the hybrid DNA preparations before transfection, 1- $\mu$ g samples of the unrestricted hybrids containing dimers of polyoma DNA were subjected to agarose-gel electrophoresis. The DNA was denatured and transferred from the gel to cellulose nitrate membranes<sup>11</sup> and polyoma-specific sequences were located by hybridisation with <sup>32</sup>P-labelled polyoma virus DNA followed by autoradiography. No radioactive band was detected in the positions of forms I or II polyoma DNA; 0.1 ng of polyoma DNA could be detected in parallel lanes. This experiment shows that the observed infectivity was due to the polyoma-pBR322 hybrid molecules and not to free viral genomes in the preparations, as a possible contamination could not exceed about 0.01%.

The results for the infectivity of the polyoma- $\lambda$  hybrids before and after restriction were essentially the same as those for the monomer polyoma-pBR322 hybrids. Less than 1 PFU per  $\mu$ g of hybrid DNA (<1 PFU per  $10^{10}$  DNA molecules) could be detected after infection of mouse cells with any of the uncleaved polyoma- $\lambda$  hybrids that contained a single copy of the polyoma virus genome, but cleavage with the appropriate restriction enzyme led to an infectivity similar to that of a molar equivalent of restricted polyoma DNA (Table 1). Of the polyoma- $\lambda$  hybrids constructed through *EcoRI* sites, seven of the eight different types of DNA molecule were infectious after digestion with *EcoRI*, but DNA from one hybrid ( $\lambda$ -Py 48), which was shown to have a deletion at one of the sites of attachment, was not infectious after such treatment. Similarly, the hybrids constructed through the *HindIII* sites, one of which is in the early and one in the late region, were not infectious as intact DNA molecules.

These experiments show that it is possible to prepare and maintain in *E. coli* strain HB101 plasmids containing two units

**Fig. 3** Electrophoresis of DNA from  $\lambda$ -Py hybrids in 1% agarose gels. The samples were digested with the following enzymes: tracks 1-7 and 13-17, *Bam*HI; tracks 8, 10, 11, 19, *Eco*RI; tracks 9, 18, *Bam*HI and *Eco*RI; track 12, *Hind*III and *Eco*RI. The samples in tracks 1, 9, 12 and 19 serve as reference for the size of fragments; the samples in tracks 11 and 12 show over-digestion with *Eco*RI, but nevertheless clearly show the release of unit length Py DNA from  $\lambda$ -Py 35 on digestion with *Eco*RI and provide the necessary reference points for known fragments of  $\lambda^+$  DNA in the digest with *Hind*III and *Eco*RI (refs 20 and 22). The hybrid phage were made as follows. The vector DNA (usually 1  $\mu$ g) was digested with the appropriate restriction enzyme and incubated with Py DNA (about 0.5  $\mu$ g digested with the same restriction enzyme) and T4 DNA ligase (0.1 units) in 66 mM Tris-HCl, pH 7.5, 10 mM MgCl<sub>2</sub>, 1 mM EDTA, 40 mM NaCl, 10 mM 2-mercaptoethanol and 0.1 mM ATP (0.1 ml) at 10 °C for 3-6 h and then 0 °C for at least 24 h and sometimes several days. In some experiments linear dimers of Py DNA were isolated by agarose-gel electrophoresis of samples of Py DNA (10  $\mu$ g) that had been digested with *Eco*RI, heated to inactivate the enzyme and then incubated with T4 ligase. The section of gel containing the linear dimers was dissolved in saturated potassium iodide solution<sup>21</sup> and the DNA adsorbed on hydroxyapatite from which it was recovered by elution with 0.4 M potassium phosphate, pH 7, and dialysed against 0.3 M NaCl and then 10 mM Tris-HCl, pH 8, and 1 mM EDTA. Linear Py DNA cleaved at one of the two *Hind*III targets was prepared by partial digestion in conditions previously shown to give no detectable fragments of Py DNA. Viable phage DNA molecules were recovered by transfection of competent cultures<sup>15</sup> of *E. coli* *r*<sub>k</sub><sup>-</sup> *m*<sub>k</sub><sup>-</sup> *recA* prepared as described by Lederberg and Cohen<sup>16</sup> or, more frequently, by *in vitro* packaging using cells that had been UV-irradiated<sup>5</sup>. Plaques screened as indicated in Fig. 4 were picked into phage buffer containing CHCl<sub>3</sub> and re-plated. After two such cycles, plate lysates were prepared and used to infect small-scale liquid cultures. From these lysates 1-l cultures were prepared by infection of cells at a m.o.i. of 1 followed by growth for 3 h with vigorous aeration. Lysis was completed by addition of CHCl<sub>3</sub> and phage recovered from the clarified lysates by precipitation with polyethylene glycol (Carbowax 6000, to 10% w/v, NaCl to 0.5 M) overnight at 4 °C. The precipitates were recovered by centrifugation, extracted with phage buffer and after clarification by centrifugation at 10,000 r.p.m. the phage were isolated by centrifugation on CsCl step gradients followed by equilibrium centrifugation in 41.5% w/w CsCl (ref. 14). Phage bands were collected and dialysed against 10 mM Tris-HCl, pH 8 and DNA prepared by phenol extraction followed by dialysis. Samples were digested with restriction enzymes as indicated above and analysed by electrophoresis in agarose gels (1% in 40 mM Tris-acetate, pH 8.2) which were photographed under UV light after staining with ethidium bromide (0.5  $\mu$ g ml<sup>-1</sup>). In some cases the gels were soaked in NaOH solutions to denature DNA fragments for transfer to cellulose nitrate membranes<sup>11</sup> and hybridisation with <sup>32</sup>P-labelled Py RNA. The fragments A, B, C and D all hybridised with the Py probe. The MW of these fragments deduced from their electrophoretic mobilities are: A,  $2.5 \times 10^6$ ; B,  $2.75 \times 10^6$ ; C,  $3.25 \times 10^6$ ; D,  $3.9 \times 10^6$ . Fragment E is characteristic of *Bam*HI digests of DNA from  $\lambda$  derivatives and is the left terminal fragment of the molecule. All operations from transfection or packaging of ligase reaction products to isolation and restriction digestion of the hybrid phage DNA were carried out in a Category III laboratory and all cultures and lysates were inoculated and handled in glove boxes, rather than laminar flow cabinets. Digested DNA was analysed in Category I laboratories.

**Fig. 4** Orientation of polyoma DNA within  $\lambda$  in the  $\lambda$ -Py hybrids. Only part of the  $\lambda$  genome is included in the diagrams showing the orientation of the polyoma DNA within  $\lambda$ . The vectors are described elsewhere<sup>6,22,23</sup>; NM 816 is a  $\lambda$ CI derivative of NM616. Targets for *EcoRI* are denoted by srl, and targets for *BamHI* and *HindIII* by sbm and shn, respectively. The orientations were based initially on the size of the fragments (determined from their electrophoretic mobility in 1% agarose gels) released by digestion with *BamHI*. In the case of the hybrids made through the *EcoRI* sites, the important fragments were A, B, C and D (Fig. 3), but fragment B ( $2.75 \times 10^6$  daltons) and fragment D ( $3.9 \times 10^6$  daltons) are the same size as fragments that would be released by the action of *BamHI* on head-to-head or tail-to-tail dimers of polyoma (2.8 or  $3.9 \times 10^6$  daltons). Heteroduplexes made between all the hybrid DNAs and their parent vectors showed, however, that all but one of the hybrids contained an inserted DNA fragment equal in length to polyoma DNA. The exception was  $\lambda$ -Py 48, which had a slightly smaller fragment inserted. The fragment in the *BamHI* digest of  $\lambda$ -Py 40 (Fig. 3, track 3) with the same mobility as polyoma DNA was, in fact, not polyoma DNA, but a fragment containing both  $\lambda$  and polyoma sequences; the orientation of the polyoma DNA in this hybrid is not shown here. Heteroduplexes between pairs of hybrids confirmed that the polyoma inserts in  $\lambda$ -Py 35,  $\lambda$ -Py 48 and  $\lambda$ -Py 57 were in the same orientation, but in the opposite orientation from those in  $\lambda$ -Py 37 and  $\lambda$ -Py 12; similarly, the orientation of the polyoma in  $\lambda$ -Py 24 was shown to be opposite to that in  $\lambda$ -Py 27. The heteroduplexes between  $\lambda$ -Py 35 and  $\lambda$ -Py 48 showed a deletion of about 0.7% of the total DNA located at 59% from one end of the molecule. This, together with the MW of fragment A in a *BamHI* digest ( $2.5 \times 10^6$ ), showed the presence of a deletion of about  $0.25 \times 10^6$  daltons (about 350 base pairs) in hybrid  $\lambda$ -Py 48 and digestion of the DNA with *EcoRI* showed that the deletion removed one of the *EcoRI* sites (srl-2) at which the polyoma and vector DNAs had been joined. Further digests of the hybrid DNA preparations with *HindIII* and digests with both *EcoRI* and *BamHI* (results not shown) confirmed these conclusions and assignments of orientation. The orientations of the polyoma DNA in the  $\lambda$ -Py hybrids made through *HindIII* sites and the determination of the *HindIII* site in the polyoma DNA at which the insertion had occurred were confirmed by an extensive analysis (by gel electrophoresis) of the digestion products formed with *BamHI*, *HindIII* and *EcoRI*, acting singly and in combination (results not shown).

of polyoma DNA linked head-to-tail at the *BamHI* site. The failure to recover hybrids that contain dimeric polyoma DNA linked to plasmid DNA or to phage  $\lambda$  DNA through the *EcoRI* site is not understood although the changes in characteristics observed during the propagation of some of the polyoma- $\lambda$  hybrids recovered by *in vitro* packaging suggest that phage genomes containing dimeric polyoma DNA were formed but were unstable. It seems that with both *red*<sup>+</sup> and *red*<sup>-</sup> phage in *rec*<sup>+</sup> or *recA* host cells the dimeric polyoma DNA is converted rapidly into monomer size by some recombinational events in the bacterial cell. None of the hybrid phage constructed through the *HindIII* site contained dimers of polyoma DNA. However, more recent results suggest that phage containing dimers of polyoma DNA can be made through the *BamHI* site although their stability is unknown.

The fact that cloned polyoma DNA, when excised at the site of joining, has an infectivity very similar to that of form III DNA derived from polyoma virions is evidence for the remarkable fidelity of the cloning procedure and the stability of a eukaryotic sequence replicated in a prokaryotic host. The finding that hybrid DNA containing only one unit length of polyoma DNA is not infectious to cells permissive for polyoma shows that intracellular excision of full-length, circular or linear polyoma DNA from the hybrid must be a very rare event. In contrast, excision of polyoma DNA from a hybrid containing a head-to-tail dimer is relatively efficient in mouse fibroblasts and probably results from legitimate recombination. A hybrid containing a head-to-tail dimer of polyoma DNA with an 800-base pair deletion in which, due to the location of the deletion (Fig. 1e), only 1.3 units of polyoma DNA are available for excision of a unit length viral DNA, had 10% of the infectivity of the plasmid containing the full dimer. This suggests that the frequency of

excision may be related to the target size for possible recombinational events. The production of SV40 virus from adenovirus-SV40 hybrids has also been observed to depend on the extent of duplicated SV40 sequences present<sup>24</sup>. The observed infectivity of hybrid DNA containing dimers of polyoma DNA resembles the results obtained by Jaenisch and Levine<sup>12</sup>, and Israel *et al.*<sup>13</sup>, who found that linear and circular oligomeric SV40 DNA was infectious to permissive cells and gave rise to SV40 particles containing monomeric DNA.

Experiments designed to test the transfer of recombinant DNA from *E. coli* to an animal cell or to an animal can only be useful if the recombinant DNA itself is potentially infectious. The demonstration that hybrid DNA containing head-to-tail dimeric polyoma DNA is highly infectious to mouse fibroblasts whereas that containing a monomeric DNA insert is not, justifies an extension of the experiment to *in vivo* studies. In these studies bacteria containing such hybrid plasmids and phage will be administered to cultured mouse cells and to mice which will then be scored for polyoma infection.

After completion of this work two reports were published on the cloning of polyoma virus DNA in the pBR322 plasmid and bacteriophage  $\lambda$  in the enfeebled *E. coli* host  $\chi$ 1776 (refs 25, 26). In one case a dimer of polyoma DNA was shown to have been cloned in  $\lambda$  but in an unstable fashion. Consistent with the results presented here that recombinants containing duplicated polyoma virus sequences are biologically active *in vitro*, these workers found that only recombinant DNA preparations containing dimer polyoma sequences were biologically active when injected into animals.

We thank Dr R. J. C. Harris, D. Titmus and other staff members of the MRE at Porton Down for their hospitality and help, and Drs R. Kamen and B. Griffin for <sup>32</sup>P-polyoma RNA.

The travel involved in this work was supported by short-term EMBO Fellowships. Financial support was provided also by the Schweizerische Nationalfonds (no. 3.114.77) and the Kanton of Zürich (to C.W.), the SRC (to K.M.) and the ICRF (to M.F.). P.G. was the recipient of a Fellowship of the Health and Safety Executive to whom we are also indebted for financial support; in particular we thank Dr D. O. Haines.

## Cytoplasmic synthesis of plastid polypeptides may be controlled by plastid-synthesised RNA

It is generally agreed that some plastid polypeptides are coded by plastid DNA and the remainder by nuclear DNA, and that some plastid polypeptides are synthesised on plastid ribosomes and the remainder on cytoplasmic ribosomes<sup>1,2</sup>. Studies on two mutant lines of barley (*Hordeum vulgare* L. 'albostrians' (M4205) and 'Saskatoon') have helped the understanding of the integration of the plastid and nucleocytoplasmic systems. In both lines a nuclear mutation is expressed as an irreversible mutation of the plastid DNA yielding pigment-deficient plastids whose segregation leads to white-striped leaves and later to pure white leaves and shoots<sup>3,4</sup>. The white leaves do not contain

plastid ribosomes and no protein synthesis can be detected in the plastids, although cytoplasmic ribosomes are present in normal amounts<sup>5,6</sup>. Immunoelectrophoresis of extracts of white leaves has failed to detect either the plastid-synthesised large subunit or the cytoplasmically synthesised small subunit of ribulose-bisphosphate carboxylase/oxygenase, or coupling factor CF<sub>1</sub>, which has three plastid-synthesised and two cytoplasmically synthesised subunits, or the cytoplasmically synthesised ferredoxin-NADP<sup>+</sup> reductase<sup>6,7</sup>. We report here that two cytoplasmically synthesised plastid enzymes<sup>8</sup>, phosphoribulokinase (EC 2.7.1.19) and D-glyceraldehyde-3-phosphate: NADP<sup>+</sup> oxidoreductase (phosphorylating) (EC 1.2.1.13), occur in considerably reduced amounts in white leaves and deduce how the plastid may control the cytoplasmic synthesis of plastid polypeptides.

Enzyme activities were determined in the clear supernatants of homogenates made from barley leaves and were carried out for each enzyme both before and after *in vitro* activation, as described in Table 1 legend. Normally pigmented leaves of M4205 gave results for the two enzymes similar to those obtained previously for several other species, in that *in vitro* activation was substantial in extracts from etiolated leaves but proportionately smaller in extracts from illuminated green leaves because illumination of green leaves causes activation *in vivo*<sup>9</sup>. Table 1 shows that plastid pigment-deficient leaves contained measurable amounts of both enzymes and that the activities increased in response to *in vitro* activation. Thus the enzymes were present in both dark-grown leaves and in leaves subjected to 48 h of illumination, their activities falling within a range of 0.5-3.6% of those of the normally pigmented leaves of M4205. Absorption spectra and their second derivatives of intact white leaves have shown the presence of small amounts of carotenoids and chlorophyll at less than 1% of the plastid pigment content of normally pigmented leaves of M4205 (T.B. and A. Meister, unpublished). Parallel experiments with 'Saskatoon' barley yields results similar to those shown in Table 1 for M4205. Note that the *Euglena gracilis* mutant W<sub>3</sub>BUL, which lacks plastid DNA, also contains very low amounts of cytoplasmically synthesised plastid polypeptides<sup>10</sup>.

Plastid pigment-deficient leaves of both mutant barley strains seem to show slightly 'leaky' inhibition of the cytoplasmic formation of phosphoribulokinase and glyceraldehyde-phosphate dehydrogenase (NADP<sup>+</sup>). This contrasts with data for genetically normal seedlings grown at high non-permissive temperatures (28-34 °C) where the newly formed parts of the leaves are free from plastid ribosomes and deficient in plastid pigments<sup>11</sup>. The non-permissive temperature may function by preventing the assembly of plastid ribosomes<sup>12</sup>. Pigment-

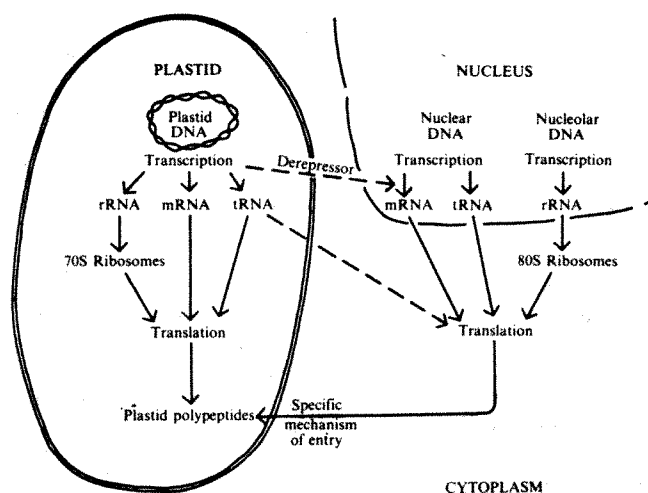

Fig. 1 Two alternative possibilities for the control of the cytoplasmic synthesis of plastid polypeptides by RNA transcribed from the plastid genome (effects expressed by broken lines).

**Table 1** Comparison of the phosphoribulokinase and glyceraldehyde-phosphate dehydrogenase (NADP<sup>+</sup>) activities of leaves of the barley mutant 'albostrians' (M4205) which either possess or are deficient in plastid pigments

	Enzyme activity (units per g fresh weight)			
	Phosphoribulokinase		Glyceraldehyde-phosphate dehydrogenase (NADP <sup>+</sup> )	
	Without <i>in vitro</i> activation	With <i>in vitro</i> activation	Without <i>in vitro</i> activation	With <i>in vitro</i> activation
7 d dark growth				
Plastid pigments normal	9.7	12.3	3.2	4.3
Plastid pigments deficient	0.15	0.37	0.09	0.15
7 d dark growth plus 2 d illumination				
Plastid pigments normal	49	51	14.1	16.6
Plastid pigments deficient	1.2	1.8	0.07	0.22

Two barley seedling first leaves were weighed and then homogenised in 5 ml of ice-cold extraction medium (100 mM Tris-HCl, pH 7.8 and 2 mM dithiothreitol) for 3 min in a Tenbroek homogeniser and the enzyme activities were determined in the supernatant obtained after 1 min centrifugation at 5,000g. Both enzymes were assayed spectrophotometrically from NAD(P)H consumption measured at 344 nm and 30 °C as previously described<sup>9</sup>. Phosphoribulokinase was activated by 12 min preincubation of 0.1 ml of extract with 50 µmol Tris-HCl, pH 7.8, 2 µmol dithiothreitol, 10 µmol MgCl<sub>2</sub>, 2 µmol ATP and 40 µmol KCl at 30 °C in a total volume of 0.38 ml. Glyceraldehyde-phosphate dehydrogenase (NADP<sup>+</sup>) was activated by 5 min preincubation of 0.1 ml extract with 50 µmol Tris-HCl, pH 7.8, 10 µmol MgCl<sub>2</sub>, 4.8 µmol EDTA, 3 µmol ATP and 5 µmol 3-phosphoglycerate at 30 °C in a total volume of 0.34 ml. Each value represents the mean from two separate leaf samples.

deficient sections of rye leaves grown at the non-permissive temperature (32 °C) contained normal amounts of the cytoplasmically synthesised photosynthetic carbon pathway enzymes, including phosphoribulokinase and NADP<sup>+</sup>-dependent glyceraldehyde-phosphate dehydrogenase, and furthermore these activities were found to accumulate within unpigmented plastids<sup>13</sup>. These pigment-deficient leaves also synthesised and accumulated the small subunit of ribulose-bisphosphate carboxylase/oxygenase in the absence of any synthesis of the large subunit<sup>14</sup>.

This work with seedlings grown at high temperatures established that the presence of functional chloroplasts is not necessary for the accumulation of cytoplasmically synthesised plastid stroma enzymes, and suggests that the failure of such enzymes to show appreciable accumulation in unpigmented leaves of the mutant barley was a result of the inhibition of their synthesis. As back-crossing experiments<sup>3</sup> have shown that the nuclear genome of the mutant barley is stable and as the inhibition of the cytoplasmic synthesis of plastid polypeptides was not found until the plastid DNA became defective, it may be deduced that the inhibition of the cytoplasmic synthesis of plastid polypeptides resulted from the loss of a product or products, arising from plastid DNA, which controlled this process. As plastid pigment-deficient leaves of the mutants and of the high temperature-grown seedlings all lacked ribosomes and did not show polypeptide synthesis in the plastids, whereas the former lacked and the latter showed the cytoplasmic synthesis of plastid polypeptides, it seems evident that such a product could not have been a plastid-synthesised polypeptide or the metabolic product of the enzymatic activity of such a polypeptide. The pigment-deficient plastids of the mutants had undergone an irreversible change in their DNA, whereas the DNA of the plastids of the heat-treated seedlings is assumed to have been unaffected, as the effects of the heat treatment were reversed by return to a permissive temperature<sup>15</sup>.

The most direct explanation for the inhibition of the cytoplasmic synthesis of plastid polypeptides in the pigment-deficient barley mutants is the assumption that they are deficient in RNA transcribed from the plastid DNA. This RNA may function in derepressing the transcription of nuclear DNA coding for cytoplasmically synthesised plastid polypeptides. Alternatively it may function as tRNA necessary for the cytoplasmic translation of mRNA coding for plastid polypeptides in agreement with the recent report that 7–9 plastid DNA cistrons of *Euglena gracilis* code for tRNA molecules which function with cytoplasmic polyribosomes and which are distinct from the

tRNA which functions in polypeptide synthesis in the plastid<sup>16</sup>. These mechanisms, shown in Fig. 1, may be considered in relation to other proposals that organelle gene products may control the nucleocytoplasmic synthesis of organellar polypeptides for mitochondria<sup>17</sup> and chloroplasts<sup>2</sup>.

Our deductions are not compatible with the 'cytoplasmic control principle' as formulated by Ellis<sup>1</sup> for the regulation of organellar protein synthesis and which states that "cytoplasmic products control organellar protein synthesis, but that the converse does not occur". We do not dispute that cytoplasmic products may control organellar protein synthesis but cannot accept the second part of this statement. On the contrary, we consider that there are also cases in which plastid products control the amount of synthesis of plastid proteins on cytoplasmic ribosomes.

# matters arising

## Short-term storage and wind power availability

ANDERSON *ET AL.*<sup>1</sup> present a further analysis of Ryle's suggestion on the role of alternative energy sources<sup>2</sup> that wind power could be used in conjunction with 150-h thermal storage to provide domestic space heating. Ryle contended that "as soon as such storage is introduced a number of alternative sources of energy can be compared on an equal basis with a nuclear system"; in other words, that wind power can not only replace nuclear power as an energy producer but, when used in conjunction with 150-h storage, can contribute just as reliably to meeting peak electricity demands. Our disagreement with Ryle is on the latter point.

In our previous paper<sup>3</sup> and our comments on Diesendorf and Westcott<sup>4</sup>, we attempted to show that 150-h storage was inadequate for matching wind generator output to the heating load and as a result would have little, if any, effect in reducing the amount of firm generating capacity needed for meeting peak demands on the electricity supply system. We believe that the data presented by Anderson *et al.*<sup>1</sup> support this view.

Figure 1 of ref. 1 shows that over the 17-yr period considered, wind power in conjunction with 150-h storage would have failed to maintain room temperature to within 3 °C of the target temperature (20 °C) for 14% of the time, while Fig. 2 shows that during the period February–March 1975 the temperature would have fallen below 17 °C for 65% of the time. We contend that the occupants would resort to supplementary direct electrical heating during such periods with the result that the peak load on the supply system would be little different from what it would have been in the absence of wind generation. Consequently, unless storage of the type advocated by Ryle could be economically provided for periods much longer than 150 h, wind power would operate only as a fuel saver.

Anderson *et al.*<sup>1</sup> also suggest that the optimum ratio of rated to annual average wind speed for a wind turbine would be closer to a value of 1.5 than the 2.3 ratio used by ETSU in Energy Paper 21, which we also adopted for our estimates. We acknowledge that such a choice of ratio would reduce the time of zero output and hence the storage requirement. However,

an estimate we have made from an analysis of 16 yr of wind data from four of the sites of ref. 3 suggests that the reduction in energy output would be well above the estimate of 20% so far as the higher wind speed sites, including offshore locations, are concerned. For such sites a mean annual wind speed of 14 knots at the standard 10 m recording height would be more typical than the 12 knots on which calculations are based in ref. 1. We estimate that, in the former case, the energy loss would be closer to 40%, a reduction which would outweigh the savings on capital cost. We agree, however, that the economic optimum is likely to be somewhat lower than 2.3 even for very windy sites, the exact value being machine design dependent. Anderson *et al.* suggest that the energy deficit resulting from operation at a ratio of 1.5 can be regained by increasing the radius of the rotor. It would seem to us that having optimised the ratio of the rated to mean wind speed at a given site for a given design of machine, the size of rotor would be maximised within the constraints of engineering feasibility.

2. Ryle, M. *Nature* **267**, 111–117 (1977).
3. Leicester, R. J., Newman, V. G. & Wright, J. K. *Nature* **272**, 518–521 (1978).
4. Leicester, R. J., Newman, V. G. & Wright, J. K. *Nature* **275**, 254 (1978).

ANDERSON *ET AL.* REPLY—Leicester *et al.* have for the most part accurately restated our quantitative results<sup>1</sup>. With reference to the need for a supplementary supply, we would stress that the system we assumed was (intentionally) the most stringent in that, even with perfect correlation between available wind energy and heating demand, the house temperatures would only just be maintained at 20 °C. Nevertheless, the lowest temperature reached over the entire 17-year period was 10 °C, at a time when the outside temperature was ~0 °C. The system was, therefore, always able to supply at least 50% of the energy required (heating demand being assumed proportional to the difference between internal and external temperatures). Even if the energy shortfall on this isolated occasion

had to be met entirely by the conventional grid, the electrical heating demand would be reduced by ~50% over that necessary in the absence of wind power, which we would not describe as 'hardly different'.

The question of turbine rating has apparently not been fully appreciated by Leicester *et al.* Our analysis (which was based on calculations involving actual wind data and not just estimates) depends only on the statistics of the wind distribution at a particular site and is otherwise completely independent of the precise value of mean wind speed. The loss in total annual energy output for a change of turbine rating from 2.3 V to 1.5 V is relatively independent of the particular site and corresponding mean wind speed as can be seen from Fig. 7 of the ETSU report<sup>2</sup>; this figure, which shows the results for seven sites, including one of the higher wind speed sites referred to by Leicester *et al.*, indicates values of this loss in the range 15–25%, rather than the 40% estimated by Leicester *et al.* The specific value of 12 knots used in our Table 2 (ref. 1) was adopted simply to allow actual figures for power output and so on to be quoted; the conclusions would have been similar for any reasonable value of adopted mean wind speed.

The optimisation of costs for a particular design is a complex problem and the engineering constraints involve not only the size of the rotor but also, for example, the limitations of gearbox torque and tower strength. The same annual energy output can be obtained by the use of a larger but more lightly-loaded rotor operating over a lower range of wind speeds, allowing the use of a smaller gearbox and alternator and reducing the structural loadings of the tower. On the basis of the relative costs given by ETSU<sup>2</sup> this will usually lead to a more economical design.

M. B. ANDERSON

MARTIN RYLE  
P. F. SCOTT

Cavendish Laboratory,  
Madingley Road,  
Cambridge, UK

1. Anderson, M. B., Newton, K., Ryle, M. & Scott, P. F. *Nature* **275**, 432–434 (1978).
2. Energy Technology Support Unit, Department of Energy, *Energy Paper 21* (HMSO, London, 1977).

TO CONCLUDE this correspondence the authors have been invited to provide a

final summary of the main points of agreement and disagreement between them.

THERE are two principal points of disagreement: (1) the extent to which wind power (with 150-h storage) can provide a reliable heating supply; and (2) the variation of net power output with aerogenerator rating.

(1) Ryle<sup>1</sup> considered the question of domestic heating demand. He concluded that wind power with the addition of 150-h storage on the consumers' premises could meet this demand at all times and thus replace an equal amount of conventional or nuclear generating plant.

In an analysis covering a six-month period, Leicester *et al.* (ref. 2 and above) found periods of a week or more during which the 150-h storage, initially full, would have been completely discharged and therefore unable to meet any of the heating demand. They pointed out that at such times there would have been little reduction in the heating demand imposed on the electricity grid and, consequently, little saving in the amount of thermal plant needed to meet peak demands.

Anderson *et al.* later proposed<sup>3</sup> a modified system with a store in which the heat output is a linear function of the energy remaining in the store. In this system as the heat output from the store fell short of that required the demand on the grid would progressively increase. They found that over a 17-year period this demand would never exceed about half the average heating load, with a corresponding reduction in the required installed thermal power station capacity. Thus, although a wind energy system in which there was no surplus capacity would be unable to supply the entire heating load, it could, nevertheless, make a significant power as well as energy contribution.

Leicester *et al.* agree that this second proposal is of interest, but further work will be required before the full implications of such a system can be assessed. (2) The disagreement on the second point is less easy to explain. Based on the analysis of wind data, the Cambridge group suggest that changing the rated speed of the aerogenerator from 2.3 to 1.5 times the mean site wind speed decreases the annual energy output by between 15 and 25% (in agreement with the data given in the ETSU paper) whereas the CEGB group, from a similar analysis, derive a figure closer to 40%. The two groups agree that the precise figure will be a function of the generator characteristics and the wind speed distribution function and this matter warrants further study.

## On an environmental model for the type Kimmeridge Clay

TYSON *ET AL.*<sup>1</sup> have proposed that Kimmeridgian coccolithic limestones were the result rather than the cause<sup>2</sup> of extreme anaerobic conditions analogous to those in the Black Sea today. Anoxic water columns develop where a salinity or temperature gradient causes density stratification which restricts circulation. However, anoxic mid-water columns develop in some areas due to high productivity in the euphotic zone<sup>3</sup>. If circulation was restricted, perhaps by topography, this process could go to extreme, therefore the suggestion of Gallois<sup>2</sup> cannot be discounted. The microlaminated marls associated with oil shales may form at maximum development of anoxic conditions. However, observations of major developments of the coccolithic limestones contradict this proposition for their origin. Also, carbonate will tend to dissolve below the O<sub>2</sub>–H<sub>2</sub>S interface<sup>4</sup>.

The Rope Lake Head Stone Band interbedded with the oil shales is bioturbated with *Rhizocorallium* and encrusted with oysters. The White Band contains distinct burrows at certain horizons and ripple cross-lamination. The evidence is conclusive, the major developments of coccolithic limestone occurred in aerated bottom water. Transpositional structures within the limestones indicate the substrate was unstable and this would account for the lack of benthos in places.

I believe the oil shales mark the maximum stand of the O<sub>2</sub>–H<sub>2</sub>S interface. Vertical movement of this interface could cause the lithological change clay–bituminous shale–oil shale, but dilution by terrigenous material can account for it equally well. In the Kimmeridge Clay both factors interact. The coccolith limestones accumulated when circulation increased. The previously anoxic water would supply concentrated nutrients, in particular HCO<sub>3</sub><sup>-</sup>, and favour the propagation of coccoliths. This model accounts for incomplete cycles, such as, bituminous shale–coccoliths–bituminous shale and is more consistent with observational evidence.

HILARY IRWIN

Department of Geology,  
University of Reading,  
Whiteknights,  
Reading, UK

1. Tyson, R. V., Wilson, R. C. L. & Downie, C. *Nature* **277**, 377–380 (1979).
2. Gallois, R. W. *Nature* **259**, 473–475 (1976).
3. Didyk, B. M., Simoneit, B. R. T., Brassell, S. C. & Eglinton, G. *Nature* **272**, 216–222 (1978).
4. Degens, E. T. & Stoffers, P. *Nature* **263**, 22–27 (1976).

TYSON REPLIES—Irwin has proposed an interesting modification of the stratified water column interpretation for the cyclic sedimentation observed in the type Kimmeridge Clay. While we apparently

agree that the sequence clay–bituminous shale–oil shale represents a transition from aerobic to anaerobic bottom conditions (coupled with the progressive development of an O<sub>2</sub>–H<sub>2</sub>S interface in the lower part of the water column) our respective interpretations for the depositional conditions of the coccolith limestones are directly opposed.

On the basis of field observations Irwin claims that the coccolith limestones were deposited in aerobic bottom conditions when the dispersal of anoxic, nutrient-rich bottom water had promoted increased propagation of coccoliths. As I have only just completed a detailed examination of the sequence I must contradict Irwin's evidence: (1) The Rope Lake Head limestone, although bioturbated, is not oyster encrusted (and is not a true coccolith limestone). (2) Only a single poorly developed horizon of bioturbation occurs in the White Stone Band coccolith limestone, reflecting what was clearly a transient improvement in bottom oxygenation (for example, associated with limited advection due to a density current). (3) The White Stone Band coccolith limestone does not contain any evidence of bottom currents, but penecontemporaneous deformation structures do sometimes resemble ripples. (4) The coccolith limestones are devoid of benthos.

The remainder of Irwin's argument contains several inconsistencies. While solution of inorganic carbonates (such as, 'seekreides'<sup>1</sup>) is an important process below the O<sub>2</sub>–H<sub>2</sub>S interface, it is not relevant to this discussion for coccoliths are at present day accumulating on the floor of the Black Sea<sup>2</sup> (despite pH values of 7.6 ref. 3). If the deposition of coccolith limestones were initiated by the dispersal of anoxic bottom water (coincidental with the development of aerobic bottom conditions) then: (1) There is no reason why 'varve-like' microlaminations should form. (2) Any microlaminations would have been destroyed by bioturbation (there is no *a priori* reason to suppose the substrate was unsuitable for benthos—especially when one considers the bioturbation in the White Stone Band). (3) This would contradict the geochemical<sup>4</sup> and palynofacies evidence (ref. 5 and personal observations). (4) It would imply that the coccolith limestones should always be underlain by oil shales (that is, sediments representing anoxic bottom conditions) which they are not. (5) According to Gallois<sup>6</sup> the decay of the resultant phytoplankton bloom would recreate anoxic bottom condition anyway. (6) A greater degree of lateral variation would be expected. Bottom water dispersal events are recorded in the stratigraphic record, but not by laminated coccolith limestones<sup>7</sup>.

Any belief in a stratification/O<sub>2</sub>–H<sub>2</sub>S interface model is incompatible with Gallois' original hypothesis<sup>8</sup> which was an alternative to the restricted basin models.

If one does believe in stratification one should accept that with the onset of stagnation the  $O_2$ - $H_2S$  interface will inevitably rise to the base of the euphotic zone (where it will participate in the plankton dynamics of the basin) unless one of several external influences disrupts the system<sup>7</sup>. Much more convincing evidence is required if Irwin seeks to replace a model which has the weight of Quaternary-Recent modern analogues behind it.

## Calcium activation of the cortical reaction in sea urchin eggs

USING sea urchin (*Echinus esculentus*) eggs broken by shock discharge, or isolated egg cortices, Baker and Whitaker<sup>1</sup> found that about  $1 \mu M$  Ca was sufficient to activate exocytosis of half the cortical vesicles. They represent this figure as an order of magnitude lower than the figure we reported<sup>2</sup> (between 9 and  $18 \mu M$ ) using *Lytechinus pictus* sea urchin isolated cortices.

However, there is no discrepancy between our results. We measured the level of calcium required for nearly complete (>95%) exocytosis, and we have recently obtained a more precise estimate of  $12 \mu M$ , determined by breaking the eggs open in the test solutions. From Baker and Whitaker's Fig. 2, they observe 95% exocytosis at a Ca concentration of  $6 \mu M$  ( $pCa = 5.2$ ). Moreover, Baker and Whitaker derive an apparent stability constant<sup>3</sup> from a Ca-EGTA binding constant<sup>4</sup> ( $pK$ ) of 11. However, in physiological media a lower binding constant is appropriate<sup>5</sup>. We assumed a  $pK$  of 10.7 in our calculations for our HEPES-buffered solutions, as this value was reported<sup>6</sup> for similar phosphate-buffered solutions. This difference in binding constant accounts for the twofold difference remaining between our calculated Ca threshold for the cortical reaction and that offered by Baker and Whitaker.

The problem of selecting the appropriate binding constant for EGTA is a general one in studies of the role of calcium. We recently attempted to estimate the primary Ca-EGTA binding constant ourselves, using calcium-specific electrodes filled with Ca-DOPP mixed with

DOPP-n<sup>7</sup>. We could only obtain accurate measurements of calcium when the apparent binding constant of EGTA for Ca was reduced in PIPES-buffered low pH (6.5) and the monovalent cation concentration was kept to 0.13 M. We measured an apparent binding constant,  $pK' = 5.3$ , corresponding to a primary Ca-EGTA binding constant of  $pK = 10.6$ . Since high pH<sup>8</sup> and high ionic strength<sup>9</sup> are both reported to reduce the primary Ca-EGTA binding constant (but see ref. 10), it seems that even our estimate for the Ca threshold of the cortical reaction ( $12 \mu M$ ) is too low.

Baker and Whitaker also suggest that ATP is needed to maintain the cortical intracellular Ca store. We found that sperm, the Ca-transporting membrane ionophore A23187, and the parthenogenetic agent urea all release Ca from the same store<sup>11</sup>. Quantitative estimates of the amount of Ca released<sup>2,12</sup> compared to the cortical reaction threshold, suggest that the store is released into a small fraction of the cytoplasm at the cortex. As the store is replenished and can be discharged again about 45 min after release (when the cortical vesicles are gone), it is unlikely to be associated with the cortical vesicles themselves. The calcium store may reside in a subsurface endoplasmic reticulum, but this has not yet been observed in the appropriate cortical region. The calcium may be bound directly to the membrane instead.

We thank Sherwin Lee for help with the Ca-sensitive electrodes.

**BAKER AND WHITAKER REPLY**—We are delighted that Zucker and Steinhardt find no serious disagreement between their results and ours.

It is unfortunate that one cannot be sure of the value of the free calcium concentration in physiological solutions buffered with EGTA to within half an order of

magnitude. As Steinhardt *et al.* pointed out<sup>1</sup> the most one can do is to specify total calcium, magnesium and EGTA concentration so that, should reliable affinity constants become available, the free calcium data may be recalculated. Although monovalent cation concentrations were not identical, a rather direct comparison of the results obtained on British and American urchins is possible because the calcium buffers used in our experiments<sup>2</sup> were made up in the same proportions of calcium, magnesium and EGTA as those specified in the study of the cortices of *Lytechinus*.

Much of the apparent discrepancy stems from Zucker and Steinhardt's somewhat peculiar definition of 'threshold' for cortical granule release as the calcium concentration giving release of 95% of the granules. Although the release of individual granules is an all-or-none process, our observations suggest that in a population of granules the rate of discharge is a smooth function of calcium concentration. Physiologically, it is likely that the abrupt onset of the cortical reaction can be attributed to the release of large amounts of calcium from a store<sup>3</sup>. In the presence of 5 mM ATP, a calcium test solution<sup>2</sup> which according to Steinhardt *et al.*<sup>1</sup> contains  $1 \mu M$  free calcium, initiates a cortical response which spreads as we have described and has discharged all the cortical granules within 2 min. At higher calcium concentrations the rate of discharge of the granules (expressed as a percentage of the total number) increases. A calcium activation curve obtained by scoring the proportion of granules remaining at 30 s has a similar half point to the data (Fig. 2a of ref. 2) for eggs subjected to high voltage discharge in solutions of different calcium concentration. Again, using the constant of Steinhardt *et al.*<sup>1</sup> the half activation point is about  $3 \mu M$ , although its position will depend on the time after addition of calcium at which the reaction is assessed. At its fastest, the discharge of cortical granules over the whole cortical fragment takes about half a minute. This is not dissimilar to the rate *in vivo*<sup>4</sup>. Without information as to the time of observation, the half point of activation in the cortices of *Lytechinus* cannot strictly be estimated, but might at its lowest be  $6 \mu M$ . At worst, as it is not clear whether concentrations of calcium less than  $12 \mu M$  cause any granule discharge in *Lytechinus*, there remains an order of magnitude difference between the two species in the lowest calcium concentration which has been demonstrated to produce a cortical response.

Although this difference in the affinity of the cortical reaction for calcium in the eggs of the British and American urchins may well have its explanation in species differences, or the uncertainties in free calcium concentration, our observations as to the critical importance of ATP in maintaining the properties of the

# THE BARR & S TROUD INTEGRATING MICRODENSITOMETER- DESIGNED TO REDUCE YOUR LABORATORY WORKLOAD

If you have a regular requirement for full quantitative cell information, it's worth checking out the Barr & Stroud GN5 Integrating Microdensitometer. With a scanning duration of only four seconds yet giving a 0.25 micron resolution, it brings speed and precision to cell preparation analysis.

The use of highest quality Leitz optics ensures reliability of results for even the smallest specimens. For histochemical and cytochemical studies, accuracy is better than  $\pm 1\%$  over an optical density range from less than 0.1 to greater than 2.5.

Area measurement, electronic masking and

narrowband illumination are just some of the other features which make this instrument a most attractive addition to your laboratory.

The GN5 Integrating Microdensitometer yields results with a speed and at a level of accuracy that far outstrips the standards that can be achieved by manual methods of study.

Designed in accordance with ergonomic principles, it's comfortable to work with too.

Start to reduce your laboratory workload by sending for full literature today. Use the journal reply system or, alternatively, contact us direct.

physiological reaction<sup>2</sup> suggest a less trivial explanation. As experiments with *Lytechinus* were performed in the absence of added ATP, the decrease in calcium affinity which results from removal of ATP in *Echinus* may well be the factor responsible for the apparent differences in calcium affinity in the two species.

### Fusion or lysis of vesicles by $\text{Ca}^{2+}$ ?

GINSBERG showed<sup>1</sup> that sonicated phosphatidylserine (PS) vesicles in the presence of large concentrations of  $\text{Ca}^{2+}$  or  $\text{Mg}^{2+}$  did not retain sucrose and he concluded that the final structures had lost the form of closed vesicles. As such, he proposes the cation effect to be one of lysis and the  $\text{Ca}^{2+}$ -PS system to be an inappropriate one for the study of membrane fusion. It is not surprising that the final product of the PS-metal interaction cannot retain solutes such as sucrose, as the vesicles collapse and internal volume is lost<sup>2</sup>. The PS membrane repeat determined by X-ray diffraction is 53 Å in 2 mM  $\text{Ca}^{2+}$ ; 67 Å in 10 mM  $\text{Mg}^{2+}$  (ref. 2) and 71 Å in 1 M  $\text{Na}^+$  (ref. 3). The term 'membrane fusion' refers to the formation of larger membranous structures by contact and mixing of the parent membranes. This is in contrast to the mixing of membrane lipids by diffusion of the components, as proposed for the dimyristoyl lecithin-dipalmitoyl lecithin system<sup>4</sup>. Recent experiments<sup>3</sup> have shown that release of contents is nearly second order in vesicle concentration and is concomitant to aggregation, demonstrating vesicle contact in leakage experiments. That  $\text{Ca}^{2+}$  induces fusion, that is, mixing of membrane components, is indicated by the formation of large cochleate structures, which on addition of EDTA, become huge vesicles capable of entrapping large molecules<sup>5</sup>.  $\text{Mg}^{2+}$  alone is less effective<sup>6</sup> but in its presence, only small concentrations of  $\text{Ca}^{2+}$  are required for obtaining larger structures<sup>2,3</sup>. Similarly, in the dimyristoyl phosphatidylglycerol-dipalmitoyl phosphatidylglycerol<sup>7</sup> and in phosphatidic acid-phosphatidylcholine vesicles<sup>8</sup>,  $\text{Ca}^{2+}$  induces mixing of the lipids, that is, fusion. Our view is that fusion requires a destabilisation of the membranes in contact until the joint membrane is arranged. Model systems are intended to be approximations to the *in vivo* systems. A definition of

membrane fusion as a process without leakage is too restrictive and so far no experiment has ruled out leakage in fusion events. In model systems better approximating the *in vivo* system, such as mixed PA/PC vesicles<sup>8</sup>, mixing and retention of contents has been demonstrated. The interactions postulated to occur between the  $\text{Ca}^{2+}$  and PS in the pure system are still relevant to the mixed systems.

### GINSBERG AND GINGELL REPLY—

The comments of Nir and Pangborn stem from an inadequate definition of membrane fusion. They claim that fusion is equivalent to the mixing of components from two contacting parent membranes. However, physiological membrane fusion apparently involves the transfer of aqueous contents from one membrane-bounded compartment to another without spillage into inappropriate spaces, as seen in phagosome-lysosome interaction and secretion. Any artificial system should fulfil this additional criterion to be biologically relevant<sup>1,2</sup>. Thus, the X-ray data cited by these authors<sup>3</sup> seem to invalidate their PS system as a paradigm for membrane fusion:  $\text{Ca}^{2+}$  converts PS into a multilayer containing no removable water. Such collapsed multilayers could result from the lysis of closed membranous forms by the mechanism we suggest<sup>1</sup>. The experiments described by Nir and Pangborn where loss of contents is reported to accompany vesicle aggregation may also be explained in terms of lysis:  $\text{Ca}^{2+}$ -induced vesicle rupture with loss of contents may provide the antecedent for immediate aggregation of the resultant membrane fragments.

Although  $\text{Ca}^{2+}$  is strongly implicated in biological membrane fusion<sup>4</sup>, there is no compelling reason to suppose that its action on dispersions of single acidic phospholipids resembles its interaction with mixed lipid membranes nor with the biomembrane systems in which fusion was first studied<sup>5</sup>. This point is underlined by the far greater  $\text{Ca}^{2+}$  sensitivity of natural vesicle fusion<sup>6</sup>. Gershfeld has recently shown<sup>7</sup> that sonicated vesicles are in a metastable state at temperatures exceed-

ing the lipid phase transition temperature. Thus, addition of divalent cations to PS vesicle suspensions may merely trigger a return to equilibrium by a variety of unknown pathways.

### Some real communities are unstable

THE mathematical stability analyses of randomly constructed food webs of Pimm and Lawton<sup>1,2</sup> have emphasised the destabilising influence of omnivory. Their examination of a number of real food webs<sup>3</sup> seems to support their hypothesis that webs with many omnivores should be rare except in insect host-parasitoid systems. However, I analysed the real food webs cited as corroborative by Pimm and Lawton, that is, those of Askew<sup>4</sup>, Force<sup>5</sup> and Richards<sup>6</sup>, and found that none meet the criterion for Lyapunov stability. The validity of the models and their inherent assumptions appears questionable.

All webs were analysed using the observed signs of interaction and Pimm and Lawton's constraints on the selection of random magnitudes for parasitoid-host and herbivore-plant interactions. Signs for variable interaction, species A and B each serving as prey or predator for the other, were arbitrarily assigned. To investigate whether the occurrence of self-limited species influenced stability, runs were repeated with self-regulation terms removed (all principal diagonal elements equal to zero). Finally, self-limitation was introduced at the lowest trophic level (plant), a criterion used by Pimm and Lawton in constructing their random webs. Analysis of Richard's web was performed twice, once with the parasitoid-host and again with vertebrate predator-prey constraints used for the predatory arthropods. In no case were any of 50 runs for either the original or adjusted webs stable.

I included only primary interactions in abstracting a matrix from Force's web. The excluded terms (dashed lines in Force's paper<sup>5</sup>) represent secondary interactions, such as the rejection of a potential host which has been previously

parasitised by another parasitoid. The existence of this exploitative competition, which has been reported for many parasitoids<sup>4,7</sup>, implies that higher order interactions are common in parasitoid communities. However, higher order terms violate an assumption of the stability analysis.

If Lyapunov stability is a relevant feature of communities and extinction of some member(s) of each community is not imminent, there are several explanations for the observed discrepancy. Perhaps stable solutions exist, but have not been discerned, as randomly selected parameter values do not exhaust all possible combinations<sup>8</sup>, and the use of unequal constraints for different trophic levels prohibits tests of qualitative instability. Natural selection may drive a community towards a restricted region of parameter space where mathematical stability is realised<sup>9</sup>.

An alternative explanation is that the community models are inadequate. Coincident with Pimm and Lawton's predictions, the instability of these webs is apparently the result of high connectance (percentage of non-zero elements in the interaction matrix), reflecting the presence of many omnivores. In fact, both of Askew's webs include omnivores whose alternate prey occupy widely separated trophic levels. This is the most destabilising form of omnivory according to Pimm and Lawton. If these webs are in fact stable, perhaps the constraints on selection of interaction magnitudes are biologically unrealistic, as the other stability parameters (connectance, number of species) are observed quantities. It has been demonstrated that as the range of constraints is narrowed, implying lower interaction intensities, the probability of a random community exhibiting stability increases. The host switching of many parasitoids and the concomitant unequal use of alternate hosts suggests that a narrower range of constraints should be used for some of the parasitoid-host interactions.

The problems associated with the community models may involve more than just the determination of actual interaction intensities and their linearity. Two assumptions underly the models and the resultant stability analyses. First, communities are considered to be definable closed systems uninfluenced by immigration and chance extinction. However, real communities are dynamic entities. The delineation of ecologically meaningful boundaries of a community can be critical to stability analysis as some unstable communities are comprised of several stable subunits<sup>10</sup>. Furthermore, Levin<sup>11</sup> has demonstrated that immigration and spatial heterogeneity can profoundly influence community stability. The second assumption is that the interactions we are attempting to estimate, competition or predation, are responsible

for both the population dynamics of the species comprising the community and its organisation. Many predators, particularly parasitoids, can greatly influence the abundance of their prey as evidenced by successful implementation of biological control, but their role in community organisation is less clear. Similarly, the role of competition in structuring communities and controlling species abundances is a hotly contested issue<sup>12,13</sup>. Therefore, in light of the current lack of understanding of the determinants of community organisation, I question the predictive value of community modelling and mathematical stability analyses.

I thank Daniel Simberloff, Stan Faeth and Donald Strong for their comments.

#### LAWTON AND PIMM REPLY—

Auerbach has overzealously applied an extremely simple model; Lotka–Volterra equations do no more than capture the shadow of real biological interactions. We used such models to generate qualitative predictions<sup>1</sup>, and deem it extremely unwise to attempt more quantitative fits to real webs. However, this does not mean that our hypotheses cannot be tested.

Our main qualitative prediction was that omnivory has a destabilising influence on food webs, the more so when predators are bigger and rarer than their prey, and have a large *per capita* effect on the things they eat. We were deliberately cautious in assessing this prediction, noting simply that it was 'encouraging' to find very complex webs in the real world in exactly those situations predicted by the models, that is amongst insect host–parasitoid interactions. More detailed analyses confirm that insect food webs do have significantly more omnivory than other webs<sup>2</sup>. Indeed none of several interesting qualitative predictions yielded by simple Lotka–Volterra models<sup>3,4</sup> are refuted by data from real food webs<sup>2</sup>. To test our hypotheses further, we would prefer to see whether these qualitative predictions still hold when the major assumptions of the models are changed, rather than try to force unmodified Lotka–Volterra equations beyond their sensible limits. For example, if incorporating spatial heterogeneity reverses our predictions (making

omnivory easier to achieve in non-parasitoid than parasitoid webs), then our results are a nonsense. We doubt whether any of the refinements listed by Auerbach will have this effect.

Far from refuting our models, Auerbach's analysis confirms our conclusion that omnivory is destabilising: it is much easier to find stable solutions for simple webs than it is for complex ones. At present, we see no evidence for claiming that the majority of persistent natural populations are best described by model analogues that are inherently unstable<sup>5,6</sup>. However, the detail needed to stabilise the models depends on the nature and rigour of the questions being asked. Auerbach suggests several possible reasons why his Lotka–Volterra models of real food webs are always unstable. Undoubtedly higher order interactions<sup>7,8</sup> (which do not violate the assumptions of a local stability analysis, but make non-equilibrium behaviour difficult to predict), the precise choice of parameter values (we put webs into the correct relative ranking: the numbers themselves were guessed, not measured, and may well have been wrong in detail?) and spatial heterogeneity are all important. The effects of spatial heterogeneity, in particular, must be incorporated before models can accurately predict observed levels of host depression by parasitoids<sup>9</sup>. (For a wide range of models of varying levels of complexity, yielding insights with different degrees of rigour, see ref. 10.)

However, Auerbach's note is valuable in drawing attention to biological details that must be important in determining the fine structure of food webs. Viewing webs as static entities with fixed links is no more than a crude beginning<sup>11,12</sup>. The concept<sup>13</sup> of webs 'resonating' between different configurations, each of low complexity, may well provide a valuable theoretical starting point for more sophisticated analyses.

We thank Mike Hassell and Simon Rallison for comments.

## Chemical Concepts in Pollutant Behavior

by I.J. Tinsley, *Oregon State University.*

The author identifies the physical and chemical properties that determine environmental behaviour, describes the processes in the natural environment that can be effective in transforming chemicals, and defines the molecular characteristics that can cause a particular compound to react in those processes. (*Environmental Science and Technology Series*)

June 1979 282 pages  
0471 03825 3 \$28.00/£14.00

## The Calculation of Molecular Orbitals

by J.C. Slater, *Massachusetts Institute of Technology.*

This examines the problem of solving the self-consistent-field equations of molecular-orbital theory within the framework of the X statistical exchange-correlation approximation. It emphasizes the concept of and computational procedure for solving the X SCF equations by the cellular multiple-scattering method (widely implemented for molecules and solids using the approximations of "muffin-tin" potentials and overlapping atomic spheres).

June 1979 112 pages  
0471 03181 X \$23.00/£11.50

## The Principles of Interferometric Spectroscopy

by J. Chamberlain (deceased);  
completed, revised and edited by G.W. Chantry and  
N.W.B. Stone, *both of the National Physical Laboratory,  
Department of Industry, Teddington.*

*The Principles of Interferometric Spectroscopy* is a basic text covering the physical and mathematical concepts and computational procedures of this now widely applied technique. A general historical background and description of the various experimental methods used is given in the introductory chapter, while chapters two, three and four cover the fundamental mathematical ideas and devices required. The application of these ideas to applied spectroscopy is dealt with in chapter nine. Chapter ten, introducing computational aspects and procedures, is primarily concerned with an outline of the ideas behind the Cooley-Tukey Algorithm and the Fast Fourier Transform.

This book is the first to bring together the whole field of interferometric spectroscopy at other than an introductory level.

April 1979 360 pages  
0471 99719 6 \$48.00/£20.00

## Radiation Detection and Measurement

by G.F. Knoll, *University of Michigan.*

A basic review of instruments and methods for the detection and measurement of ionizing. It includes an analysis of electronics and pulse processing in instrumentation systems, treatment of passive radiation detectors, and consideration of shielding and background. It offers pragmatic guidance for the inexperienced detector user.

May 1979 832 pages  
0471 49545 X \$35.95/£17.25

## Computer Assisted Studies of Chemical Structure and Biological Function

by A.J. Stuper, W.E. Brugger and P.C. Jurs.

This describes a new research approach to the study of structure-activity relations and explains techniques that can be retrospectively used to uncover previously overlooked chemical activities. It also describes the methods of chemical structure information handling, chemical structure storage, and computer generation of molecular structure descriptors.

June 1979 232 pages  
0471 03896 2 \$31.00/£14.50

## Holographic-Interferometry

by C.M. Vest, *University of Michigan.*

A unified, comprehensive, self-contained treatment of theory, practice, and application, including related coherent optical techniques. It emphasizes the quantitative evaluation of holographic interferograms of both opaque and transparent objects, explaining how tools such as the laser and holograph are being applied to present-day measurement problems. It applies clear, simple, physical reasoning to present practical information and data and circumvents complicated mathematics wherever possible. (*Pure and Applied Optics Series*)

April 1979 480 pages  
0471 90683 2 \$36.50/£18.30

## Carbon-13 NMR Based Organic Spectral Problems

by P. Fuchs and C.B. Bunnell, *both of Purdue University, Indiana.*

A collection of 125 spectral problems with special emphasis on the use of carbon-13 NMR techniques.

*Contents:* Spectral Problems; Appendix 1: A General Protocol for Solving Organic Spectral Problems; Appendix 2: Solved Problems; Appendix 3: The Curphey-Morrison Additivity Constants for Proton NMR Chemical Shift Approximation; Appendix 4: Selected Reference List.

April 1979 316 pages  
0471 04907 7 (paper only) \$11.50/£5.75

## Geochemical Processes: Water and Sediment Environments

by A. Lerman, *Northwestern University, Illinois.*

In this book the author explains what happens when waters, solids, and gases interact in the earth's surface environment. He introduces the broad picture of global geochemical cycles and treats in detail the individual processes responsible for the major fluxes of materials on land, in waters, and to a lesser degree, in the atmosphere. Figures, tables, and data summaries are included.

Announcing

# Molecular and Biochemical Parasitology

## Aims and Scope

The journal provides a medium for the rapid publication of investigations of the molecular biology and biochemistry of parasitic protozoa and helminths. The main subject areas covered are:

- |                                   |                                    |
|-----------------------------------|------------------------------------|
| (1) biochemical composition;      | (6) membrane structure and         |
| (2) biochemistry of low molecular | function, including transport;     |
| weight compounds;                 | (7) regulation;                    |
| (3) structure, properties and     | (8) genetic aspects;               |
| function of macromolecules;       | (9) action of antiparasitic drugs; |
| (4) biosynthesis and degradation  | (10) biochemical aspects of        |
| of macromolecules;                | host-parasite relationships.       |
| (5) intermediary metabolism;      |                                    |

Papers will only be accepted for publication if they fall within these areas, if they contain original work of high scientific quality and if they have been well written. There will be no page charges.

## Basis for an ethical system

Stuart Sutherland

*Beast and Man: The Roots of Human Nature.* By Mary Midgley. Pp. 377. (Harvester Press: Brighton, Sussex, 1979.) £7.50

*Beast and Man* has been widely praised by the litterateurs who contribute to the book pages of the surviving intellectual weeklies. It is a long, rather rambling book, in which it is difficult to discern a clear connected argument. Its main aim seems to be to establish a secure basis for ethics. Mary Midgley argues that, like other animals, man has many inborn drives: these drives can only come to fruition within the context of a culture. She argues that what is good for man must depend upon the nature of his motives: moral reasoning consists of the attempt to harmonise conflicting emotions and to give priority to those which are most deeply ingrained in our nature. It will be a comfort to scientists that she believes the scientific study of human nature can assist in making ethical decisions by revealing more about man's true nature. A second theme running through the book is that we are part of the Animal Kingdom and of the Universe and that one principle of morality is that man should have respect for other animate beings and indeed for the inanimate universe.

In preparing the ground for her own thesis, she assails previous views of the nature of goodness, but she frequently seems to espouse the mistakes of which she accuses others. For example, she attacks Aristotle for arguing that the ultimate human value must be the development of that function which is unique to man and not shared by other animals. She rightly remarks that "it must be shown separately that this differentia is itself the best human quality, that it is the point where humanity is excellent as well as exceptional". Yet later in the book she writes: "Should we therefore say that everything we want is good? In a minimal sense this is right...but...we must go further...because of a competition amongst our various wants. What is good in a stronger, more considered sense must be wanted not just by someone's casual impulse, but by *him as a whole*" [her italics]. The meaning of "him as a whole" is obscure, but supposing

it were to turn out — as it might — that hatred for outgroups was an inborn human characteristic, she would seem to be committed to the proposition that it was thereby good. Edward Wilson has emphasised that the mechanism of evolution depends on the selection of genes that survive and she criticises him for erecting the survival of the individual gene into a principle of morality, but she herself seems to be committing the same fallacy in arguing that whatever is an essential part of human nature must be good.

When she wishes to recommend a given course of action she tells her readers that it is "natural". She believes that: "Respect for other forms of life is certainly a natural feeling. It is not a mere inclination, it is a feeling that we must not destroy certain things — and one that is not isolated, but forms part of our central system of standards". She provides no arguments to show that this feeling is any more natural than delight in wanton cruelty; nor does she provide criteria for deciding that something is natural nor even attempt any clear definition of what the word means. The fact that something forms part of the "central standards" of some people cannot automatically make it good: many societies have as part of their central system of standards a belief in the duty to avenge themselves and their families for slights.

Much of her book seems to be based almost on word play. For example, she insists that the word "rational" is used not merely to describe the behaviour of someone who makes the correct moves in solving intellectual problems, but also the behaviour of someone who acts consistently from a well harmonised set of emotions. Her point about the use of language is right, but it does not seem to advance her argument and it is not clear that it is any more difficult to harmonise a set of bad motives than a set of good ones.

She frequently embarks on arguments that look promising, but they tend to peter out. For example, she uses a cunning analogy to attack one of Wilson's arguments: he believes that understanding how ethical systems have evolved and how our reasoning about morality is controlled by the nervous system will throw light on the nature of ethics. She points out that

discovering how the workings of the brain enable us to do mathematics will not illuminate the nature of mathematics: to understand that we must understand the relationship between numbers, how mathematical proofs work, and the standards by which to judge the correctness of a mathematical calculation or proof. But she makes no attempt to explain what the standards are that are used in moral argument or decision making. It is easier to agree about the canons of mathematics than to resolve a disagreement about ultimate goals.

Although the book as a whole is both unsatisfactory and unsatisfying it does contain nuggets of robust common sense, many of which are well put even if they are not entirely new. For example, in arguing for the continuity of man and the Animal Kingdom, Mary Midgley points out that we often project our own evil on to animals and use a double standard in evaluating their behaviour and our own. It is unreasonable to despise the fox who kills hens for sport more than those who ride to hounds. Again, she points out that we cannot abnegate from instilling a culture and norms in our children — an adult who tries to adopt a non-committal position and tells the child he need not accept a particular ideal until he is old enough to judge for himself is in effect saying "I do not take this seriously and nor need you" and is likely to instil norms of "timidity, shiftiness, and dilettantism". She proposes a sensible if slightly vague resolution of Wilson's dilemma over how altruism towards unrelated members of the same species may have originated: it may have been built on filial and parental instincts, and indeed affectionate gestures between adults mimic those made by parents to children and children to parents.

In view of her obvious sincerity and high-mindedness and the importance of the endeavour, it is a pity Mary Midgley has not produced a more cogent and carefully argued book, but most previous attempts to establish a secure basis for an ethical system have proved equally unsuccessful.

Stuart Sutherland is Professor of Experimental Psychology at the University of Sussex, Brighton, UK.

## Neurosecretion

Simon H. P. Maddrell  
Jean J. Nordmann

A survey of the most important aspects of neurosecretion which lays special emphasis on the mechanisms and principles of the process. The authors show how neurosecretory systems are designed to operate efficiently in conjunction with other physiological systems.

While written especially for upper undergraduates and postgraduates of pharmacology, endocrinology and neurobiology, the book is also an ideal introductory survey for researchers in this specific area, or in related fields.

## Protein denaturation

*Physicochemical Aspects of Protein Denaturation.* By S. Lapanje. Pp 331. (Wiley: Chichester, UK, and New York, 1978.) £19.50.

THERE has been no significant, full-length review of protein denaturation since 1970. Although many fundamental principles had been laid at the time, there has been a steady advance in the detailed understanding of denaturation in the intervening years. Further, the biological and industrial significance of conformational change and stability is more widely appreciated today, and more chemists, biochemists and physicists are ready to devote time and energy to rigorous studies of the dynamics of protein structure. The field of protein denaturation has a distinguished history, starting with Ramsden's observation in 1902 that "a dead frog placed in saturated urea solution becomes translucent and falls to pieces in a few hours". Anfinsen's thermodynamic hypothesis of folding, the concept of limited pathways, quantification of protein stability, the hydrophobic interaction and prediction of tertiary structure all owe something to denaturation studies, and many of these areas are still under active study.

This monograph sets out to survey the physicochemical basis of denaturation and therefore leaves the reader to apply the fruits of this approach to his own field of work and interest. Methods appropriate for studying denaturation are described; in each case a self-contained account of the fundamentals is given, with examples taken from conformational studies on proteins and polypeptides and references to recent reviews for further detail. Techniques include hydrodynamic, optical, light scattering, NMR and hydrogen exchange, although calorimetry, surprisingly, considering the author's interest, is given only passing mention.

The largest section of the book comprises a survey of experimental results obtained with a range of perturbants including heat, pH change, urea and guanidine, inorganic salts, organic solvents, and detergents. This draws together a wealth of detail from the literature and enables the reader to compare the different and frequently rather specific effects of these modes of denaturation. The results are well illustrated with data from original papers. It is useful to have the literature presented objectively and without the constraint of a particular theoretical viewpoint.

The chapter on the thermodynamics of denaturation, an aspect to which the author has made significant contributions, contains a good discussion of the two-state hypothesis and an up to date account of calorimetric studies and of the thermodynamics of thermal denaturation.

Although it is mentioned in several places that the denatured states may differ depending on the mode of perturbation, I could find no discussion of the dependence of derived thermodynamic parameters on the definition of the denatured state. Also, the values of  $n$  in the relationship  $K^1_D = Ac^n$  surely range wider than 12 to 20 — probably a misprint. The interpretation of biphasic kinetics of unfolding and refolding of proteins in terms of the proline isomerisation model is a particularly hot issue at the present moment and the short chapter on kinetics of denaturation provides a useful background to the various ways in which such experiments have been treated. This leads into a final chapter dealing more with interpretation of kinetic and thermodynamic experiments, particularly with respect to the mechanism of folding of globular proteins and the nature of the interactions of denaturants with proteins. As regards the latter, the author seems to favour the direct binding of urea molecules to a protein as a driving force in denaturation, and it is an interesting exercise to try and fit an alternative explanation to the results he quotes purely in terms of change in water structure.

This monograph is valuable as an unusually well organised survey of a massive literature. I found it stimulating, not because of strongly argued personal ideas, but because of the creative apposition of the different experimental approaches and interpretations which have been used in this field. It is, however, encouraging to find that his thermodynamic hackles are capable of being roused when his basic convictions are challenged (see p295). This review is valuable also in that the author emphasises the complexity of deriving and assigning thermodynamic parameters from systems as complex as proteins in multicomponent solvents.

The book is well produced and well illustrated. The index contains the reviewer's favourite enzyme but omits "two state transition". One is enormously impressed by the feat of writing (over 300 pages) in what is, to the author, his third language. Only occasionally is there a misplaced and, very occasionally, a misleading nuance. Most of these are so obvious that in more happy and responsible days one might have expected the publisher to have brought them to the author's attention. The duplication of equation 2-26 and the confusing layout of Table 4.4 also fall into this category. Nevertheless, this is a monograph that will be an essential reference work for all those concerned with the stability and dynamics of proteins and provides excellent value for money.

Roger H. Pain is Professor of Physical Biochemistry at the University of Newcastle upon Tyne, UK.

# NEW TITLES IN THE EARTH SCIENCES

## A Dynamic Stratigraphy of the British Isles

**R. Anderton** (U. of Strathclyde), **P. H. Bridges** (Derby College of H.E.), **M. R. Leeder** (U. of Leeds) and **B. W. Sellwood** (U. of Reading)

Stratigraphy is a topic of central importance in any scheme of geological studies, but it has long been regarded as being dull and overburdened with tedious detail. This book draws on the latest findings from offshore exploration and on the contributions of the various Earth sciences in an attempt to break the traditional mould. It presents the geological evolution of a part of the Earth's crust as an illustrated description of events—a truly fascinating story.

**CONTENTS.** *Part one* THE CRUSTAL FOUNDATIONS. *Part two* THE IAPETUS OCEAN AND THE BUILDING OF THE CALEDONIDES. *Part three* THE NORTH ATLANTIC CONTINENT AND HERCYNIAN CONTINENTAL MARGIN. *Part four* THE BRITISH ISLES ON THE EUROPEAN CONTINENTAL MARGIN.

246 x 189mm, 320 pages, 203 line drawings, 4 photographs. £7.95 net paperback (0 04 551028 8), £15.00 net hardback (0 04 551027 X). September 1979.

## Geology for Civil Engineers

**A. C. McLean** and **C. D. Gribble** (U. of Glasgow)

Geology for civil engineers aims to provide civil engineering undergraduates with the geology they need, and to avoid spurious claims on their time with much that may be of geological interest but little engineering relevance. The authors hope to meet the professional need to appreciate the nature of soils and rocks and their distribution below ground surface, and to comprehend and understand the engineering significance of geological reports.

**CONTENTS.** Introduction; Minerals and rocks; Superficial deposits (soils); The distribution of rocks at, and below, the surface; Sub-surface (ground) water; Geological exploration of an engineering site; Rocks and civil engineering; The principal geological factors affecting certain engineering projects.

234 x 156mm, 320 pages, 110 line drawings, 28 photographs. £5.95 net paperback (0 04 624002 4), £11.00 net hardback (0 04 624001 7). August 1979.

## The Interpretation of Igneous Rocks

**K. G. Cox** (U. of Oxford), **J. D. Bell** (U. of Oxford) and **R. J. Pankhurst** (British Antarctic Survey)

*The interpretation of igneous rocks* is unique among books on igneous petrology in showing how data derived from petrographic, geochemical and field studies can be used in the formulation and testing of petrogenetic hypotheses, and in dealing with methodology as an important aspect of igneous petrology.

**CONTENTS.** Fractionation in igneous processes; Compositional variation in magmas; Phase diagrams—introduction; Ternary systems—1; Ternary systems with solid solutions; The interpretation of two-element variation diagrams; Petrographic aspects of volcanic rocks; Quaternary systems; Experimental work on natural basaltic and allied rocks; Water-bearing rock systems; Compositionally zoned magma bodies and their bearing on crystal settling; Petrographic aspects of plutonic rocks; The interpretation of data for plutonic rocks; Trace elements in igneous processes; The use of isotopes in petrology.

234 x 156mm, 464 pages, 175 line drawings, 23 photographs. £8.95 net paperback (0 04 552016 X), £18.00 net hardback (0 04 552015 1). September 1979.

**GEORGE ALLEN & UNWIN**  
LONDON BOSTON SYDNEY

## Invertebrate Palaeontology and Evolution

**E. N. K. Clarkson** (U. of Edinburgh)

This major new textbook deals comprehensively with all the main groups of invertebrate fossils and introduces evolution and palaeoecology largely in the context of a systematic treatment of taxa which continues to be the essential basis of undergraduate studies.

**CONTENTS.** *Part one* GENERAL PALAEOONTOLOGICAL CONCEPTS: Principles of palaeontology; Theory of evolution; Origin and early diversification of metazoans. *Part two* INVERTEBRATE PHYLAs: Sponges, archaeocyathids and stromatoporoids. Cnidarians; Bryozoans; Brachiopods; Molluscs; Echinoderms; Graptolites; Arthropods; Exceptional faunas.

246 x 189mm, 336 pages, 164 multi-component line drawings, 23 photographs. £7.95 net paperback (0 04 560008 2), £15.00 net hardback (0 04 560007 4). September 1979.

## Petrology of the Metamorphic Rocks

(*Textbook of petrology*, vol. 3)

**Roger Mason** (University College, London)

This is a long-awaited introduction to metamorphic petrology which, in common with its companion volumes, emphasises a petrographic approach. The presentation of petrography in relation to modern understanding of metamorphism stands in contrast with most of the other books on the subject.

**CONTENTS.** *Part one* METAMORPHIC ROCKS IN THE FIELD: Metamorphism and metamorphic rocks; Field relations of metamorphic rocks; Description and identification of metamorphic rocks in the field. *Part two* METAMORPHIC ROCKS UNDER THE MICROSCOPE: The chemical and mineralogical compositions of metamorphic rocks; Contact metamorphic rocks; Dynamic metamorphic rocks; Regional metamorphic rocks of Precambrian shield areas; Regional metamorphic rocks of Palaeozoic orogenic belts. I: Regional metamorphic rocks of Palaeozoic orogenic belts. II: Regional metamorphic rocks of Cainozoic orogenic belts; Metamorphic rocks of the ocean floor; Metamorphic rocks of the upper mantle. *Part three* METAMORPHIC ROCKS IN THE LABORATORY: The study of metamorphic reactions; Isotope geology of metamorphic rocks; Electron-probe microanalysis; Metamorphic rocks and the evolution of the Earth.

234 x 156mm, 272 pages, 118 line drawings. £5.95 net paperback (0 04 552014 3). November 1978.

## Petrology of the Sedimentary Rocks, 6th edn

(*Textbook of petrology*, vol. 2)

**J. T. Greensmith** (Queen Mary College, London)

This is a completely revised, reorganised and more concise edition of a widely used textbook. Emphasis is placed upon the classification and description of modern and ancient sediments, and the wider contexts of their origin, transport, deposition and distribution are also introduced. A firm base is thereby provided from which to proceed to more advanced sedimentology texts.

**CONTENTS.** Introduction; Fragmental deposits; Transportation; Sedimentary structures; Rudaceous deposits; Arenaceous deposits; Argillaceous deposits; Limestones; Magnesian limestones and dolomites; Siliceous deposits; Ferruginous deposits; Carbonaceous deposits; Phosphatic deposits; Evaporites.

234 x 156mm, 244 pages, 92 line drawings, 13 photographs. £5.95 net paperback (0 04 552012 7), £11.00 net hardback (0 04 552011 9). October 1978.

Announcing a New Quarterly Journal from Wiley

# BIOPHARMACEUTICS & DRUG DISPOSITION

The Journal will publish original reports of studies in biopharmaceutics and pharmacokinetics, especially those which have a direct relation to the therapeutic use of drugs. This includes bioavailability and other human pharmacological studies, and therapeutic response and toxicity related to plasma and other tissue concentrations of drugs. Research on the design of drug dosage regimens, on factors affecting the disposition of and clinical response to drugs, and on the treatment of overdose, based on pharmacokinetic principles, will be accepted. Papers on analytical methodology, *in vitro* drug metabolism, and on animal models, will also be published, provided that they either facilitate the preceding types of investigation, or may otherwise be related to the use of drugs in man. The Journal will also carry review articles on specific subjects within the scope as defined above.

## Semiconductors textbook

*Semiconductors*. Second edition. By R. A. Smith. Pp. 523. (Cambridge University Press: Cambridge, New York and Melbourne, 1978.) Hardback £27.50; paperback £8.95.

THE publication of a second impression of any major textbook provides an indication of its value: its publication twenty years after the original edition in a field that had been developing very rapidly over most of this period gives further proof of the lasting value of the treatment which has not dated significantly. When R. A. Smith's book appeared in 1959 it provided the most detailed text on the then new and rapidly developing subject of semiconductor physics, with special emphasis on transport and optical properties. Now that the subject has reached what might be called mature age, the new edition is to be welcomed as a continuation of this tradition, with some significant modifications in order to introduce new topics and to update the bibliography. With the avowed intention of keeping the total volume constant, this was not an easy task, and the author may be congratulated on having, on the whole, succeeded rather well. As one part of the adopted strategy the reader is increasingly referred to the other major text by the same author, *Wave Mechanics of Crystalline Solids* (Chapman and Hall: London, 1961) and this means that the student will find the use of two textbooks more imperative than with the original edition.

The layout of material departs significantly from the original, partly to accommodate the additional subjects and partly to streamline the treatment. The first four chapters on elementary properties, energy levels, impurities and carrier concentration remain virtually unchanged. The original very extensive chapter on electron transport has been altered in several respects, one of which is the omission of the Boltzmann equation as the basis for the treatment of transport theory—in this reviewer's opinion, a retrograde step at the level aimed at in the book. Scattering mechanisms and high field effects are relegated to separate chapters and a new section is introduced on conduction at very low temperatures. Optical and high-frequency effects have been significantly expanded, the behaviour in high electric fields has been coupled with that in high magnetic fields to take account of recent advances, including the important transferred electron phenomena and carrier freezeout.

The original chapter dealing with the determination of semiconductor properties has been removed; and the chapters describing the properties of elemental and compound semiconductors have been shortened into one, no doubt on the reasonable basis that the volume of information on properties of semiconductors is so vast that it requires reference to specialist texts for any but the most elementary data. Instead, we have a short chapter on band structure and the effective mass approximation describing some recent developments such as the LCAO and the k.p methods and the pseudopotential. Another new chapter on "Some special topics" deals with excitonic molecules, electron-hole droplets, polarons and polaritons, tunneling in heavily doped materials, and the tunnelling spectroscopy and laser action in semiconductors, among others. The book closes with another new chapter on amorphous semiconductors providing a brief outline of this topic on a mainly descriptive basis.

The bibliography has been brought up to date in some of the more important respects but there is no pretence of giving complete listings which would become rapidly dated.

The overall impression is a very favourable one: this is still one of the most authoritative and comprehensive texts on this subject in one volume,

with a very detailed treatment of transport and optical properties and with a less detailed discussion of the band structures and of other physical properties of semiconductors. There is no significant discussion of any semiconductor devices, again on the reasonable assumption that this would make the text either much too long or too superficial.

One criticism of the presentation is the relatively inefficient use of diagrams: the information content of many of these is low for their size and some are too closely similar to represent real value—for example, Figures 13.3 and 13.4 giving the temperature dependence of the forbidden gap in germanium and in silicon. More economy in this respect would have permitted the inclusion of a wider range of information.

These are, however, minor criticisms of an otherwise excellent text which will continue to provide the basis of both undergraduate and postgraduate lecture courses and will represent a useful general reference text. The price, especially of the paperback edition, is very reasonable and the presentation is excellent throughout.

A. K. Jonscher

A. K. Jonscher is Professor of Solid-State Electronics at Chelsea College, University of London, UK.

## Standard reference work on the plastids

*The Plastids: Their Chemistry, Structure, Growth and Inheritance*. Second edition. By J. T. O. Kirk and R. A. E. Tilney-Bassett. Pp. 960. (Elsevier/North Holland/Biomedical: Amsterdam, New York and Oxford, 1978.) Dfl337; \$149.75.

THE first edition of *The Plastids* has become something of a standard reference book. Because of the great advances which have taken place since this first edition was published, it was already beginning, after only a decade, to show its age. The authors have therefore undertaken a complete revision of their work, and the new enlarged edition contains a vast amount of additional information not earlier available. Each chapter now begins with a useful summary which allows the reader to find his way quickly and easily through the book.

The present volume attempts to cover the whole plastid literature, and

therefore necessarily goes over much of the same ground as previously. The text is first class and references to new work are included as appropriate. The figures and diagrams contain much new material clearly set out. But I was greatly disappointed by the re-use of many old electron micrographs; in view of the rapid advances which have taken place in electron microscopical studies of plastids since 1968 I suspect that many of the authors credited with the pictures used would have welcomed the chance to offer new micrographs of material treated by more modern methods of fixation. The quality of printing of the micrographs, in spite of the glossy paper used and in view of the remarkably high price of the book, is generally poor and indistinct and many of the pictures lack the contrast which the originals undoubtedly possessed. The pictures carried forward from the first edition seem to have suffered most in this respect.

Part I, *Chemistry, Structure and Function of Plastids*, is greatly enlarged and now comprises chapters 1–12 (pp.1–250), an increase of 160 pages. This part of the book will be of great value to someone wishing to have a

good general summary of the properties of chloroplast proteins, lipids and pigments and an account of the fine structure of the different plastid types. There are also excellent short chapters on chloroplast permeability and photosynthesis. Dr Kirk is to be congratulated on the excellence of the summary of the new biochemical material and the development of ideas which he presents in this section.

Part II discusses the "Inheritance and Genetic Behaviour of Plastids" and is written by Dr Tilney-Bassett (chapters 13–22, pp.251–521). The form of presentation has obviously been completely rethought. New material has been incorporated, some old material discarded and a major rearrangement has been carried out. The new data on plastid mutagens and the causes of mosaic variegation are particularly valuable and the problem of sorting out of plastids is examined well. The origin and stability of chimaeras is discussed adequately, although the description demands a prior knowledge of the ontogeny of the shoot apex. The sections dealing with the reasons for the stability of periclinal chimaeras and for the existence of mericlinal chimaeras are acceptable but are sufficiently important to warrant a more extended treatment in the context of a discussion of plastid behaviour in higher plants. However, an expert who already knows the sort of details he is looking for is very likely to find them in this as in other sections, and the comprehensive subject, taxa and author indexes, will guide him well.

Chapter 22, which concludes Part II, is a completely new one which describes plastid inheritance in *Chlamydomonas*. It is a particularly helpful chapter and brings into focus the insight which the use of a unicellular plant can give to critical studies on extra-nuclear genes. As *Chlamydomonas* can be grown in accurately controlled conditions, it can be conveniently subjected to precise experimental manipulations; this is of particular importance in studying the expression of such genes.

Part III, written by Dr Kirk, examines the "Biochemical Basis for Plastid Autonomy and Plastid Growth" (chapters 23–28, pp.525–862). While keeping to the same general form of the first edition, it includes a mass of new information. For example, the section on biosynthetic capabilities now runs to 100 pages against a previous 30, an indication of an area of most rapid development in the past decade. Throughout Part III great care has been taken to ensure a good balance in the presentation. The whole topic of chlorophyll synthesis has now been assembled in one unit in the new volume, as opposed to the scattered treatment it received in the first edition, and de-

tails of modern work on the synthesis of  $\delta$ -aminolaevulinic acid and its conversion to protochlorophyll are included. In the past decade much information on nucleic acids and protein synthesis has been obtained and this is well discussed in chapter 26. The section on plastid development (chapters 27 and 28) has been expertly updated.

Part IV (chapter 29, pp.875–894) gives us the benefit of the authors' joint views of the directions in which future research may be expected to proceed. The coverage of references generally is good up to 1976, but the immense work of printing such a large volume means that the literature between 1976 and 1978 (date of publication) has of necessity had to be largely ignored. It is therefore satisfying to note that the literature already contains papers on several of the topics outlined jointly by the authors in

Part IV.

This edition of *The Plastids* is more readable than the earlier edition, but it is definitely not for beginners. However, workers in this very wide field will find an immense store of information and references to the literature. For such a large book there are remarkably few printing errors and grammatical inexactitudes. The efforts of revising *The Plastids* has been well worthwhile; the volume is very impressive. So too, unfortunately, is the price, which will put it beyond the grasp of all but the most dedicated of research workers. It will, however, find a proper place on library shelves in departments of biochemistry and plant sciences throughout the world.

F. R. Whatley

F. R. Whatley is Sherardian Professor of Botany at the University of Oxford, UK.

## Techniques at low temperature

*Experimental Techniques in Low-Temperature Physics*. Third edition. By G. K. White. Pp. 331. (Clarendon, Oxford University Press: Oxford 1979.) £15.

GENERATIONS of graduate students (including the present reviewer) were brought up on earlier editions of Guy White's book, which for years remained the only available supplement to the unwritten body of lore handed down by one's predecessors and supervisor and colleagues. It is a detailed exposition of the how of experimental physics at low temperatures: how to attain the low temperature, and how to measure it when you have got it; not only how to set about designing cryogenic apparatus, but also how to translate the design into a functioning and (one hoped) leakless reality. The third edition has been reworked more thoroughly than its predecessor, and is the better for it. Some of the less used sections have been pruned to make way for new material reflecting the growing emphasis on work below 1 K, and the whole book has generally been brought up to date.

The eleven chapters deal in succession with the production and storage of liquefied gases, heat exchangers, thermometry, heat transfer, temperature control, cryostat design, cooling with  $^3\text{He}$ , adiabatic demagnetisation, vacuum techniques, and with the physical properties of solids at low temperatures. There are substantial appendices giving tabular data on: vapour

pressures of cryogenic liquids; platinum resistance and thermoelectric thermometry; relevant physical properties of elements at room temperature; electrical resistivity; and on the thermal contraction and thermal conductivity of typical constructional materials. There is an extensive (and international) list of suppliers of the cryogenic equipment, components and materials referred to in the text.

White's book no longer stands alone, of course; there are also, for example, the admirable little text *Low Temperature Laboratory Techniques* by A. C. Rose-Innes (English Universities Press: London, 1973), as well as the excellent but more specialised works by O. V. Lounasmaa (*Experimental Principles and Methods Below 1 K*; Academic: London, 1974) and by D. S. Betts (*Refrigeration and Thermometry Below One Kelvin*; Sussex University Press: Brighton, UK, 1976); but it probably remains unique in the amount of useful practical detail which is included, and in covering so wide a sweep of low temperature physics and engineering.

It is a pleasure to welcome the third edition of *Experimental Techniques in Low Temperature Physics*, and to commend it to a new generation of research workers. It is readable, it is packed with ideas and information culled from laboratories all over the world, and it has an extensive and up-to-date bibliography. It is a book which every designer or user of low temperature apparatus will wish to have at his elbow.

P. V. E. McClintock

P. V. E. McClintock is Senior Lecturer in the Department of Physics at the University of Lancaster, UK.

# ANNOUNCING BEHAVIOURAL BRAIN RESEARCH

*An International Journal*

## Aims and Scope

Behavioural Brain Research is intended to provide a forum for studies in the Neurosciences where the primary research focus is concerned with brain mechanisms of behaviour. It provides a medium for early publication of articles from such areas as:

Anatomy, Ethology, Neurology, Pharmacology, Physiology, Psychology and Zoology.

Behavioural studies as such will not be encouraged unless they are relevant or contribute to work in one of the other fields.

## Type of Papers

1. Full Length Papers - giving the findings of original research. These papers will be published within 6 months or less, after review.

2. Short Communications - which describe a novel method, technique or apparatus or results which have reached a stage where they are ready for a preliminary communication to other workers in the field. Short communications will be published in the first available issue.

3. Review Articles - a limited number of relevant review articles will be published. Similarly, long research papers with extensive review sections could be considered, especially where a connected series of studies is given which provide a coherent picture when compiled together.

# International Journal of Remote Sensing

**The official journal of the Remote Sensing Society**

This new international quarterly journal will begin publication in January 1980. It will cover all aspects of the fast-developing subject of remote sensing and its applications and will be directed towards the increasingly important areas of environmental monitoring, pollution detection and surveillance, together with conservation and earth resources studies.

It will be of interest to workers in industrial and non-industrial countries. It will be of value to government, academic, commercial and industrial workers concerned with research and development in remote sensing of the earth's land surface, remote sensing of the sea, coastal regions and marine environment, and with remote sensing of the atmosphere.

The journal will publish scientific papers describing original work as well as review papers.

**EDITORS:** The academic standards and policy of the journal will be supervised by the Remote Sensing Society. The journal will have a Board of Editors drawn from the Society's contacts throughout the world and will be so constituted as to provide full geographical and subject coverage. Dr J. van Genderen will be the Executive Editor of the journal.

Volume 1 Number 1 is scheduled for January 1980.

Subscription price: approximately £25.00 per volume of four issues.

For further information and/or free specimen copy (when available) please write to the Marketing Manager, Taylor & Francis Ltd, Rankine Road, Basingstoke, Hampshire, England.

*Manuscripts for consideration should be sent to Dr J. van Genderen, Fairey Surveys Ltd, Reform Road, Maidenhead, Berks. SL6 8BU, England.*

**TAYLOR & FRANCIS LTD**

10-14 Macklin Street, London WC2B 5NF

# newly on the market

**Ion chromatograph.** The Dionex Model 16 chromatograph permits analysis of electrolytes in physiological fluids. Determination of serum phosphate and sulphate levels is useful in the monitoring of patients undergoing kidney dialysis treatment. Ion chromatography has been shown to be a powerful tool in monitoring these levels.

**Circle No. 93 on Reader Enquiry Card.**

**Pansorbin cells.** Calbiochem-Behring. Pansorbin cells are a preparation of killed and hardened cells of *Staphylococcus aureus*, Cowan 1 strain, which bear a coating of immune globulin-binding protein A on the surface. One milligram of cells will bind a minimum of 12  $\mu$ g of human IgG. Some preparations will bind as much as 20  $\mu$ g of human IgG per mg. Pansorbin cells are provided in a 10% w/v suspension of packed cells in PBS buffer containing sodium azide as a preservative. The suspension is stable under refrigeration at 4°C for at least 4 months. Pansorbin cells can be ordered in 1 g, 10 g or 50 g quantities.

**Circle No. 94 on Reader Enquiry Card.**

Several of the products described on these pages will be exhibited at the XIth International Congress of Biochemistry, which will be held in Toronto in July. If you would like more details of these and other products described here, circle the appropriate number on the enquiry card bound inside the cover.

**Evaporator-Concentrator.** Savant Instruments have introduced a new evaporator-concentrator, the Speed Vac concentrator, which yields virtually 100% sample recovery with eluates, hydrolysates, extracts and dialysed solutions.

**Circle No. 95 on Reader Enquiry Card.**

**Restriction endonucleases.** Bethesda Research Laboratories. The Concept kit I: restriction endonucleases from BRL provide an opportunity to introduce molecular biology to the student laboratory. The Concept kit I is designed for the execution of five separate experiments illustrating concepts such as the recognition specificity of restriction endonucleases and physical analysis of DNA structure and organisation.

**Circle No. 96 on Reader Enquiry Card.**

**Size exclusion chromatography system.** Du Pont. Fast, accurate, low-cost molecular weight distribution (MWD) analysis of polymers and resins is made possible with the Du Pont high performance size exclusion chromatography (HPSEC) system, which gives precise information on the MWD of a material. By quickly and accurately separating molecules according to their size, the HPSEC system enables polymer analysts to plot an MWD curve. Most analyses can be performed in minutes.

**Circle No. 97 on Reader Enquiry Card.**

**Glucose-enzymatic assay.** Bio-Rad Laboratories have introduced a glucose-enzymatic assay for use in an ultraviolet micro procedure that is specific for the quantitative determination of glucose in serum, plasma, cerebrospinal fluid and urine. The procedure is based on a coupled enzyme method and utilises hexokinase and glucose-6-phosphate dehydrogenase. The assay is rapid, sensitive and accurate.

**Circle No. 34 on Reader Enquiry Card.**

**Ninhydrin reagent kit.** Pierce. Nin-Solve is a most convenient way to prepare an ethylene glycol monomethyl ether-based ninhydrin reagent solution. The Nin-Solve kit includes two components needed to prepare a ninhydrin reagent working solution; one is 900 ml of a ninhydrin containing Piersolve-sodium acetate buffer solution, the second is a measured ampoule of titanous chloride. Add the titanous chloride to the ninhydrin solution following the simple directions and the working reagent is ready. Nin-Solve is ideal for amino acid analysers which contain 1-l ninhydrin reagent reservoirs. With Nin-Solve you also have the option of preparing just the amount of ninhydrin reagent you need.

Circle No. 99 on Reader Enquiry Card.

**Micro-protein dialysis concentrators.** Bio-Molecular Dynamics. A selection of negative pressure micro-protein dialysis concentrators are now available from Bio-Molecular Dynamics. These are self-contained systems that can simultaneously dialyse and concentrate up to 1,200-fold, with 90 % recovery, completely unattended. Different models, including autoclavable units, provide a selection of predetermined, quantitative final volumes from 50 to 1,000  $\mu$ l.

Circle No. 100 on Reader Enquiry Card.

**Ultrasonic dismembrator.** Dynatech. As well as providing highly efficient cell disruption in a wide range of biological, medical and associated research fields, the 300-W solid state ultrasonic dismembrator from Dynatech Laboratories is powerful enough to drive general purpose cleaning tanks and pipette cleaners. This ultrasonic unit can also be used to accelerate chemical reactions by ensuring a closer association of the reacting agents.

Circle No. 101 on Reader Enquiry Card.

Dynatech dismembrator

**Biotin/avidin system.** Vector Laboratories is introducing a new line of biochemicals and immunochemicals which utilise the principle of the biotin-avidin interaction. The most recent products are 14 different biotinylated lectins, and avidin conjugates such as fluorescein-avidin, rhodamine-avidin, ferritin-avidin, horseradish peroxidase-avidin and agarose-bound avidin. Also available are biotinylated antibodies to immunoglobulins from a variety of species and a custom biotinylation service.

Circle No. 102 on Reader Enquiry Card.

**Multi-wrist shaker.** Lab-Line Instruments has introduced the No. 3587 multi-wrist shaker. This has been designed to simulate hand mixing from very gentle shaking to vigorous agitation. A solid state speed control assures accurate continuous regulation and reproducibility of speeds. The electronic timer is calibrated in minutes for preset timing up to 1 h and has a separate setting for continuous operation. The heavy cast iron body is specifically designed to eliminate creeping when properly loaded. Eight three-fingered clamps are positioned on side arms to accommodate flasks, jars, bottles or test tubes.

Circle No. 103 on Reader Enquiry Card.

## APPOINTMENTS VACANT

### UNIVERSITY OF HONG KONG LECTURESHIP/ ASSISTANT LECTURESHIP IN GEOGRAPHY

Applications are invited for a post of Lecturer/Assistant Lecturer in Geography. Applicants should possess a good honours degree in Geography with postgraduate experience in Population Studies and in Cartography. Preference will be given to candidates with research and teaching experience in China or Japan and Korea.

Annual salaries (superannuable) are: Lecturer HK\$63,540 × 4,260 to 72,060 BAR 76,320 × 4,260 to 106,140; Assistant Lecturer HK\$46,260 × 4,320 to 59,220. (£1 = HK\$10.55 approx). Starting salary will depend on qualifications and experience.

At current rates, salaries tax will not exceed 15% of gross income. Housing at a rental of 7½% of salary, education allowances, long leave and medical benefits are provided.

Further particulars and application forms may be obtained from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, or the Assistant Secretary (Recruitment), University of Hong Kong, Hong Kong. Closing date for applications is 15 August 1979.

2346(A)

### PLANT BREEDING INSTITUTE Maris Lane, Trumpington, Cambridge CB2 2LQ. HIGHER SCIENTIFIC OFFICER/SENIOR SCIENTIFIC OFFICER

**CYTOGENETICS DEPARTMENT**  
A research worker with experience in plant cytogenetics/cell biology is required for three years to participate in and be responsible for parts of a programme funded by the Ministry of Overseas Development to study the cytogenetics and cell biology of endosperm development and grain quality in cereals with special attention to grain shrivelling in wheat-rye genotypes including triticale.

Candidates should have a 1st or upper 2nd class honours degree in an appropriate biological science and at least two years postgraduate experience in plant cytogenetics/cell biology or related research.

The appointment will be as Higher Scientific Officer (£4,101 to £5,448 per annum) or Senior Scientific Officer (£5,154 to £6,898 per annum). At least four years relevant postgraduate experience is required for appointment as Senior Scientific Officer.

Applications with curriculum vitae and names and addresses of three referees should be sent to the Assistant Secretary (Establishment), quoting reference ODM/47, by 27 July 1979.

2279(A)

### UNIVERSITY OF NOTTINGHAM PHYSICS OF AIR POLLUTION DISPERSION

A graduate in physics, environmental science or engineering is required to join a team studying the influence of sulphur dioxide on crop growth. The successful applicant will investigate the turbulent dispersion of SO<sub>2</sub> in the lower atmosphere using a computer-controlled acquisition system which he will establish at a field site. Experience in computer programming and/or field work would be useful. The research project is supported by the Department of the Environment for three years. A suitably qualified applicant may register for a higher degree.

Salary on the scale £3,689 to £4,232 pa. Application with curriculum vitae and names and addresses of two referees should be sent as soon as possible to Dr M. H. Unsworth, Environmental Physics Unit, University of Nottingham, School of Agriculture, Sutton Bonington, Nr Loughborough, Leics. LE12 5RD.

2315(A)

### UNIVERSITY OF ZAMBIA Applications are invited for the following posts in the SCHOOL OF MEDICINE:

- PROFESSOR in Surgery
- ASSOCIATE PROFESSOR/  
SENIOR LECTURER in  
Microbiology/Parasitology
- CHIEF TECHNICIAN  
in Anatomy

For posts a and b candidates should have a good academic qualification and considerable experience in their fields of specialization. For the post of Chief Technician, candidates should have either a degree (Life Science), HNC in Medical Laboratory Technology, City and Guilds of London Institute in conjunction with IST or Science Laboratory Technician Advanced Certificate with at least 5 years experience in Histological or Anatomy Techniques.

Salary scales: Professor K8,616 to 9,135 pa, Associate Professor K8,232 to 8,616 pa, Senior Lecturer K7,608 to 8,016 pa, Chief Technician K5,316 to 6,324 pa (£1 sterling = K1.65). The British Government may supplement salaries as follows, posts a) and c) in range £4,182 to 6,042 pa (sterling) for married appointees and £1,986 to 3,456 pa (sterling) for single appointees; for post b) in range £4,350 to 5,154 pa (sterling) for married appointees and £1,968 to 2,568 pa (sterling) for single appointees (reviewed annually and normally free from tax) and provide childrens education allowances and holiday visit passages.

Detailed applications (2 copies) with curriculum vitae and naming 3 referees to be sent direct to the Registrar, University of Zambia, PO Box 2379, Lusaka, Zambia by 14 August 1979. Applicants resident in the UK should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address.

2344(A)

### UNIVERSITY OF DUNDEE

Applications, from candidates who hold or are about to obtain a good Honours degree in Biochemistry or related subject, are invited for appointment as a

#### RESEARCH ASSISTANT

to work with Dr. P. R. Baker, in the University Department of Surgery at Ninewells Hospital and Medical School, on a study of the effects of cholestasis on cellular transport and protein binding of bile salts by the liver.

The appointment is supported by a SHHD grant and will be available for three years from 1 September 1979, or some other agreed date. Initial salary at an appropriate point within the range £3,689 to £4,232 (to be reviewed from 1 October 1979). Superannuation under USS. Possibility of registration for a higher degree.

Applications, quoting Reference EST/54/79J and containing full details of qualifications and experience and the names of three referees, should be sent to The Secretary, The University, Dundee DD1 4HN by 12th July, 1979. Informal enquiries may be made to Dr. P. R. Baker, Department of Surgery, Ninewells Hospital and Medical School, Dundee.

2325(A)

### UNIVERSITY OF EDINBURGH Grant Institute of Geology SENIOR TECHNICAL OFFICER

Required to assist with the development of geochemical analytical techniques and with the routine instrumental analysis of geological materials. The equipment available comprises XRF, XRD, electron microprobe, AA (flame and flameless), C-N elemental analyser and a well-equipped wet-chemical laboratory. Routine analytical duties will involve preparation of materials, setting up and operating analytical equipment and the computer processing of data using computer programs already written. The post will involve working with and instructing academic staff and research students. Experience in one or more of the above or related analytical techniques would be an advantage. Qualifications required are HNC or equivalent. Salary on the scale £3,984 to £4,758 p.a. (under review) REF: NS259.

Application forms can be obtained from the Personnel Office, University of Edinburgh, 63 South Bridge, Edinburgh EH1 1LS. Telephone 031-556 2930.

2288(A)

## Microbial Biochemist for Fermentation Development

The Fermentation Development Department based at the Worthing site is concerned with the development of fermentation and enzymatic processes for the production of antibiotics and related substances. As a result of proposed expansion, a Microbial Biochemist is required to join a multi-disciplinary team working on all aspects of industrial fermentation processes.

Applicants should possess a good honours degree in Biochemistry or Microbiology preferably with some post-graduate experience.

The position requires an innovative approach combined with an ability to organize the work of one or two technical assistants.

The normal large company benefits will apply, and if you are interested you should write to, or telephone, Mr A D Caws, Senior Personnel Officer, Beecham Pharmaceuticals, Clarendon Road, Worthing, West Sussex, BN14 8QH — Telephone (0903) 39900/ Extension 233 — for an application form.

2309(A)

# Beecham Pharmaceuticals

**EUROPEAN SCIENCE FOUNDATION  
EUROPEAN TRAINING  
PROGRAMME  
in  
BRAIN AND BEHAVIOUR  
RESEARCH  
TRAINEESHIPS**

Traineeships of three, six or rarely nine months are offered to promising young scientists working in the area of brain and behaviour research in order to broaden their skills and knowledge in a field other than but related to their own. The grants are given to allow them to learn a particular technique abroad for which training is not offered in their own country. The trainee is expected to return to her/his original post upon termination of her/his training so that her/his institute will in turn be able to benefit from newly acquired skills.

All applications have to be accompanied by a letter of recommendation by the sending institute and by a letter of acceptance from the receiving institute. Preference is given to post-docs under the age of 35.

**TRAVEL GRANTS**

Travel grants are awarded to allow young research workers to visit another laboratory in connection with an on-going research project or to participate in international meetings and symposia. In addition special grants are to be awarded to students to enable them to take part in the yearly meetings of the European Neuroscience Association (ENA) which this year will take place in Rome on September 10-14.

Applications should be accompanied by letters of recommendation from the sending institute and of invitation from the institute to be visited. Applicants should be postgraduate research workers with the exception of applications to attend the yearly ENA meeting. In this particular case preference is given to postgraduate students.

The deadline for completed applications is *March 15 and September 15*. Further information and application forms may be obtained from:

# Lancashire

County Council

COLLEGE OF AGRICULTURE

SCIENCE DEPARTMENT  
APPOINTMENT OF LECTURER

Applications are invited for the post of lecturer in the Department of Sciences. The duties will involve lecturing in Agricultural Chemistry, Animal Nutrition and related topics to a range of certificate and diploma courses as well as assisting in soil science and nutrition laboratory classes.

Candidates preferably should have an appropriate degree qualification or be completing such a course this Summer.

Salary to be within the Burnham Scales for staffs of Farm Institutes Grade 1A £3,192 to £5,334 (under review), the starting point dependent on approved qualifications and experience.

Further details and application forms, which should be returned within 14 days of the appearance of this advertisement, may be obtained from the Principal Agricultural Officer, Lancashire College of Agriculture, Myerscough Hall, Bilsborrow, Preston, PR3 0RY. Telephone: BROCK (0995) 40611

2286(A)

**IMPERIAL CANCER RESEARCH  
FUND**

**TECHNICIAN/  
RESEARCH OFFICER**

(1) required to assist in our Membrane Physiology Laboratory on projects involving the regulation of cellular metabolism and growth. Experience of cell culture techniques, column chromatography and gel electrophoresis desirable. Two years experience in a biochemistry laboratory essential. Reference MP1.

(2) to work in the Tumour Virus Genetics Laboratory on projects involving the analysis of nucleic acids of mammalian cells and viruses and the molecular cloning of eucaryotic genes. Experience in the preparation and standardisation of restriction enzymes, cell culture techniques, nucleic acid purification and gel electrophoresis would be desirable. Reference TVG1.

HNC or Degree in biological science, but school-leavers with two science 'A' levels may be considered. Salary range £3,600 to £5,250. For further information and application form write or telephone, quoting the above reference, to Miss S. M. Hurley, Imperial Cancer Research Fund, Lincoln's Inn Fields, London, WC2 on 242 0200 ext. 305.

2340(A)

**UNIVERSITY OF  
NEWCASTLE  
UPON TYNE**

**DEMONSTRATOR IN THE  
DEPARTMENT OF PSYCHOLOGY  
Applications are invited for a post of  
DEMONSTRATOR**

in the Department of Psychology tenable for a period of three years. Applicants should have a good honours degree in psychology, and preferably a postgraduate qualification. Some knowledge of computing would be an advantage. The person appointed would be expected to organise and share in the running of practical classes and also to undertake some tutorial teaching.

Salary will be at an appropriate point on the Grade 1B (Bar) scale £3,775 to £5,488 per annum operative from 1st October 1979, according to age, qualifications and experience. Membership of the appropriate University superannuation scheme will be required.

Applications, giving full details of age, qualifications and experience, together with the names and addresses of two referees, should be sent to the Head of the Department of Psychology, The University, Newcastle upon Tyne NE1 7RU not later than 13th July 1979. Please quote reference N.

2356(A)

**UNIVERSITY OF BRADFORD**

**2 Year FIXED TERM  
LECTURESHIP  
in Physics**

Applications are invited from suitably qualified physicists for the above post commencing October 1979. The research interests of the School of Physics lie in Physical Electronics and Nuclear Structure Physics; applicants should be qualified to pursue research in one of these fields. Consideration given to applicants completing a PhD this summer. Salary within the range £4,232 to £8,452 per annum (under review). Further details and application forms (to be returned by 13 July 1979) obtainable from the Registrar, Post Ref. PY/L/28/X, University of Bradford BD7 1DP.

2300(A)

**UNIVERSITY OF  
MANCHESTER**

**DEPARTMENT OF CHEMISTRY AND  
ARTIFICIAL KIDNEY UNIT,  
Withington Hospital  
RESEARCH FELLOW**

Applications invited from postdoctoral analytical chemists with a strong interest in medical research for a joint medical/chemical research programme on trace metal uptake through artificial kidney machines. The work will involve chemical analysis of aqueous and clinical samples for trace metals, by flameless A.A.S., and fundamental research into metal ion transfer across dialysis membranes; it will demand a high level of scientific ability. Experience of similar work is desirable. Starting salary in the range of £4,333 to £5,199 p.a. Superannuation. Contract period 2 years, starting as soon as possible. Further details from Dr. J. P. Day, Department of Chemistry, University of Manchester M13 9PL (phone 061-273 7121 ext 5374), to whom applications with full curriculum vitae should be sent as soon as possible.

2310(A)

**THE MIDDLESEX  
HOSPITAL MEDICAL  
SCHOOL**

(University of London)

Department of Biology as Applied to  
Medicine

A Research Assistant is required to work on the development of the mouse mammary gland with reference to invasiveness. The appointment would be for two years starting from October 1, 1979. While experience in cell biology would be an advantage, applications from recent graduates would be welcomed. Salary according to age and experience, up to £5,304 p.a. including London allowance. Applications, together with the names of two referees to Professor L. Wolpert, Department of Biology as Applied to Medicine, The Middlesex Hospital Medical School, London W1P 6DB.

2323(A)

The research organisation of Synthelabo, an Internationally recognized European Pharmaceutical Group located in Paris requires a

# SENIOR TOXICOLOGIST

To lead a team responsible for various projects within a developing toxicology group in the department of Biology.

The high success rate and rapid growth of this pharmaceutical group is related to the quality of people they employ and their continued commitment to research and development.

Applicants can be either male or female and should be a PH.D with at least 5 years post-doctoral experience in toxicology and preferably with industrial experience as well. Suitably qualified veterinarians and pharmacists with relevant experience will also be considered for the post.

Candidates should possess a good working knowledge of French and English and should also be conversant with the GLP regulations for Toxicology.

A realistic salary can be expected and relocation assistance will be available together with other financial benefits. All applications will be treated in the strictest confidence and should be sent directly to Mr J. Brault at the following address:

Synthelabo 58 Rue De La Glaciere 75013 Paris

W198(A)

## MEAT RESEARCH INSTITUTE SCIENTIFIC OFFICER

A vacancy exists in the Protein Section of the Meat Structure Division.

The project involves the study of enzymes capable of producing a tenderizing effect on meat.

The person who fills the post will be substantially responsible for studying the effect of neutral proteinases and should therefore be capable of working independently.

The work will involve protein fractionation techniques and enzymology, and experience in this field would be an advantage.

Qualifications: Degree in a relevant subject. Previous experience in protein chemistry and enzymology desirable.

Salary: £2,839 to £4,415. Starting salary depending on qualifications and experience. (Salaries are subject to review.)

Permanent, pensionable post. Application forms and further details from Personnel Officer, Meat Research Institute, Langford, Bristol BS18 7DY. Closing date for return of application forms July 12, 1979. 2348(A)

## POSTDOCTORAL POSITIONS IN VANCOUVER

Positions are currently available for studies on 1) the control of phosphatidylcholine biosynthesis in animals and 2) interactions between animal viruses and cell membranes. Stipends begin at \$12,200/annum. Apply with Curriculum Vitae, list of publications and names of 3 referees to Dr. Dennis E. Vance, Dept. Biochemistry, Univ. of British Columbia, Vancouver, BC V6T 1W5 Canada. W192(A)

## KENYATTA UNIVERSITY COLLEGE — KENYA

Applications are invited for the post of

### ASSOCIATE PROFESSOR

in the DEPARTMENT OF ZOOLOGY. Applicants must have a PhD in Zoology together with high level experience in University teaching and research. The appointee will be expected to teach undergraduates, supervise the work of post-graduate students and carry out personal research. Applications will be considered from persons specializing in any area of Zoology. The areas of specialization already represented in the Department are Ecology, Marine Biology, Freshwater Biology, Parasitology and Immunology, Arthropod Biology, Physiology, Ichthyology, Developmental Biology and Mammalogy. Salary scale: Associate Professor: K£3,864 to £4,488 pa (K£1 = £1.28 sterling). The British Government may supplement salaries by £5,784 pa (sterling) for married appointee and £3,876 pa (sterling) for single appointee (reviewed annually and normally free from tax) and provide childrens education allowances and holiday visit passages. Family passages; FSSU or SSSF; non-contributory medical scheme; subsidized housing/housing allowance; various allowances. Detailed applications (2 copies) with curriculum vitae and naming 3 referees to be sent direct to Registrar, Kenyatta University College, PO Box 43844, Nairobi, Kenya by 12 August 1979. Applicants resident in the UK should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address. 2319(A)

## AGRICULTURAL RESEARCH COUNCIL'S POULTRY RESEARCH CENTRE KING'S BUILDINGS WEST MAINS ROAD EDINBURGH EH9 3JS SCOTLAND

### NEUROPHYSIOLOGIST

Applications are invited for the post of HSO/SSO in the Ethology Department of the above Centre. The post is for a neurophysiologist to investigate the responses of alimentary receptors in relation to the control of food intake in poultry. The work will involve a study of receptors at the peripheral level using electrophysiological recording techniques. The work may be extended at a later date into the central nervous system. Applicants should have training in neurophysiology and an interest in sensory physiology and animal behaviour. (Ref. No. 799).

**Qualifications:** First or upper second class honours degree in an appropriate subject with at least two years relevant postgraduate experience and preferably with a PhD. Entry at SSO level requires at least 4 years postgraduate experience. **Salary:** In scale £4101 to £5,448 at HSO level and £5,154 to £6,898 at SSO entry. (Salaries currently under negotiation). Entry at the higher level requires at least 4 years post-graduate experience. Non-contributory superannuation scheme. 22 days annual leave plus 10½ public/privilege holidays. 1½% of salary is to be paid towards the Widows and Childrens Fund.

Application forms can be obtained from the Secretary at the above address. These forms should be completed and returned not later than 31st July 1979 quoting our reference number.

2289(A)

## KING'S COLLEGE HOSPITAL MEDICAL SCHOOL (University of London) Denmark Hill, London SE5 8RX JUNIOR MEDICAL LABORATORY SCIENTIFIC OFFICER 'B'

required for the Chest Unit in this Medical School. Work will involve contact with patients and assisting doctors with research into diseases of the lung. Minimum requirements, 5 'O' levels, 4 in Science subjects including maths, day release available. Post suitable for school leaver. Salary according to age, qualifications and experience.

Applications, in writing, giving full details should be sent to the Secretary of the Medical School at the above address. Closing date 13th July 1979.

# Nuclear Power Station Physicists

Challenging opportunities for young qualified physicists exist at Hinkley Point Power Station. The station situated on the Somerset coast near Bridgwater, in fine countryside, has four power reactors on the site which provide a wide range of technical, operational, engineering and safety problems. Applications are invited from recently qualified physicists, mathematicians or engineers to join a team dedicated to the solution of those problems.

We are looking primarily for young newly qualified staff for whom the salary would be in the range

**£4110 to £6035**

but suitable applicants with some relevant

experience would be considered for a more senior post within a salary range

**£5375 to £7050**

A self financing productivity payment is also payable and the salary scales are currently under review.

Terms and conditions are excellent and fringe benefits include relocation assistance where appropriate.

If you are interested please write for an application form AF/1 from the Personnel Manager, Bedminster Down, Bridgwater Road, Bristol BS13 8AN. Please complete and return quoting vacancy number R106/79/ N.

2359(A)

South Western Region

## Leeds Area Health Authority (Teaching) Western District RESEARCH OFFICER (EPIDEMIOLOGY)

Research Officer (Scientific Officer Grade) is required to assist with studies of aetiology and distribution of lymphomas and leukaemias in the Yorkshire Region.

The study would be conducted from Leeds and involve the officer in interviewing and data analysis work in a variety of hospitals throughout Yorkshire. Applicants should have a broad education either in epidemiology, biology or social sciences and should possess a higher degree or have previous experience of population studies. The post which is currently available is for one year in the first instance renewable for a further two years.

Further particulars can be obtained from Dr. R.A. Cartwright, Yorkshire Regional Cancer Organisation, Cooridge Hospital, Leeds. Tel. Leeds 673411.

The salary will be on the Scientific Officer scale (N.H.S.) £3,486 to £4,275 per annum.

Applications obtainable from the Sector Personnel Officer, Leeds General Infirmary, Great George Street, Leeds LS1 3EX.

Closing date 16th July, 1979

2297(A)

## MRC CLINICAL RESEARCH CENTRE (NORTHWICK PARK HOSPITAL)

**WATFORD ROAD, HARROW, MIDDX. HA1 3UJ**

We require a PhD Pharmacologist and a Technician with a BSc or HNC both with experience in experimental cancer chemotherapy or in evaluating toxicity of antitumour drugs. The work, supported by a national institutes of health contract awarded to Dr. G. Gregoriadis is related to the use of Liposomes in cancer chemotherapy. The appointment will be for two years on a salary scale from £3,883 to £6,080 pa plus £502 LA.

Application form may be obtained from Mrs. J. Tucker-Bull, 01-864 5311 ext. 2685. Please quote ref. 111/1/2/NIH. Closing date July 14th, 1979.

2328(A)

## IMPERIAL COLLEGE UNIVERSITY OF LONDON DEPARTMENT OF CHEMICAL ENGINEERING AND CHEMICAL TECHNOLOGY

Applications are invited for the following position: Research Officer to work with the materials technology research group under the direction of Professor J. R. A. Pearson. The group is engaged in experimental and theoretical work on polymer chain dynamics (using relaxation, light scattering and computer simulation methods), polymer rheology, polymerisation reactors and polymer processing operations. Applicants should have a PhD in physical chemistry, physics or chemical engineering, previous experience with polymers being an advantage. Initial salary in range £4,250 to £7,145 pa plus £502 London allowance.

All applications, including a curriculum vitae and the names of two referees, should be sent to Dr. K. E. Bett, Department of Chemical Engineering, Imperial College, London SW7 2BY.

2272(A)

## CHARING CROSS HOSPITAL MEDICAL SCHOOL (University of London) LECTURER IN ANATOMY

Applications are invited for the above post. Candidates should possess a medical qualification or a higher degree in Anatomy or a cognate subject and special consideration will be given to those with an interest in neuroanatomy.

Salary on non-clinical Lecturer scale, i.e. £4,232 (£4,776 at age 26 or over) — £8,452 p.a. plus £502 London Weighting Allowance.

Applications in writing with names and addresses of two referees to The Secretary, Charing Cross Hospital Medical School, The Reynolds Building, St. Dunstan's Road, London W6 8RP, by 23rd July. (Ref: 016/8)

2353(A)

## MEDICAL RESEARCH COUNCIL VIROLOGY UNIT ENZYMOLOGIST PROTEIN BIOCHEMIST and NUCLEIC ACID BIOCHEMIST

Two vacancies exist for postdoctoral research scientists with experience in enzymology/protein biochemistry or nucleic acid biochemistry to work on a variety of molecular biological problems involving Herpes Simplex Virus and other mammalian virus systems.

Previous experience with virus systems is advantageous but not essential.

The appointment will be for three years. Salary on an appropriate point on Grade 2 of the non-clinical scientific staff scale. Applicants should send a Curriculum vitae giving full details of qualifications and experience and the names and addresses of three professional referees to: Professor J. H. Subak-Sharpe, Institute of Virology, University of Glasgow, Church Street, GLASGOW, G11 5JR, by 1st August, 1979.

2290(A)

## KENYATTA UNIVERSITY COLLEGE — KENYA

Applications are invited for the post of ASSOCIATE PROFESSOR IN THE DEPARTMENT OF CHEMISTRY. Candidates must have a PhD in Chemistry and considerable teaching experience at University level, at least at Senior Lecturer level. Further qualifications in Education or experience in the training of graduate teachers would be advantageous. The appointee will be expected to teach in the BEd and MSc programmes and to carry out and supervise research in his/her areas of specialisation. He/she will also be expected to be capable of providing academic and administrative leadership in the department. Salary scale: Associate Professor K£3,864 to £4,488 pa, (K£1 sterling = £1.28). The British Government may supplement salary by £5,784 pa (sterling) for married appointee or £3,876 pa (sterling) for single appointee (reviewed annually and normally free of all tax) and provide children's education allowances and holiday visit passages. Family passages; subsidised housing; SSSF or FSSU: non-contributory medical aid scheme. Detailed applications (2 copies) with curriculum vitae and naming 3 referees should be sent by airmail to the Registrar, Kenyatta University College, PO Box 43844, Nairobi, Kenya by 13 August 1979. Applicants resident in the UK should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address.

2298(A)

## CARDIOTHORACIC INSTITUTE LONDON

Applications are invited for two posts:-

- (1) Postdoctoral
- (2) Recent graduate

Appointments supported by a grant from the Multiple Sclerosis Society for a three year period to study mechanisms of cell accumulation and the action of drugs on this process, with particular reference to experimental allergic encephalitis. The work will involve *in vivo* experiments on cell accumulation, utilizing isotopic techniques recently developed in this laboratory. The graduate assistant can expect to be involved in extensive animal handling. The graduate appointee would be encouraged to register for a PhD. The postdoctoral appointee may be eligible for nomination to a lectureship in immunopharmacology.

For further information contact Dr J. Morley on 01-352 8121 Extn. 4194.

Please apply to Mr R.A. Perkins, Cardiothoracic Institute, Fulham Road, SW3 6HP with details of experience.

2365(A)

UNIVERSITY OF  
RHODESIA  
LECTURESHIPS/SENIOR  
LECTURESHIPS

Applications are invited for the following posts:

**BOTANY:** Applicants must have a relevant first degree and, preferably, a postgraduate qualification and relevant experience. Competence in one or more of the following fields will be advantageous: Anatomy and Morphology; Microbiology and Plant Physiology.

**CHEMISTRY:** The Department has lectureship vacancies in Physical and Inorganic Chemistry. Applicants must be suitably qualified with university or research experience. In addition the Department has responsibility for courses in Pharmaceutical Chemistry for B. Pharmacy degree students and, therefore, special interests or experience in pharmaceutical or medical applications of Chemistry would be an advantage.

**COMPUTING SCIENCE:** Applicants must have qualifications and experience in Computing Science. A knowledge of statistical methods will be an advantage.

**CROP SCIENCE — SCHOOL OF AGRICULTURE:** Applicants must have a relevant first degree and, preferably, an appropriate higher degree and relevant experience in Crop Science.

**ELECTRICAL AND MECHANICAL ENGINEERING:** Applications are invited from persons with Engineering Degrees and postgraduate experience for Lectureship posts in: (a) the Department of Electronic and Power Engineering (experience desirable in Electronic Power Systems, Electrical Machines and Electromagnetics); (b) the Department of Mechanical Engineering (Experience desirable in Thermodynamics, Heat Transfer and Mechanical Design).

Subject to University permission earnings up to a specified limit per annum for consultancy may be retained in full in addition to basic salary.

**ZOOLOGY:** Applicants must have a relevant first degree. A higher degree and postgraduate experience is desirable. Preference may be given to applicants with competence in one or more of the following fields: Vertebrate Zoology; Terrestrial Ecology; Genetics and Parasitology.

**SALARY SCALES AND CONDITIONS OF SERVICE.**

Salary (Approx. Stg. Equiv.):  
Senior Lecturer £7,088 × 275 to £7,913 × 292 to £9,373 p.a.  
Lecturer Grade I £6,429 × 242 to £7,397 p.a.  
Lecturer Grade II £3,969 × 208 to £5,009 × 242 to £6,219 p.a.

Commencing salary according to qualifications and experience. Family passages and allowances for transport of effects. Installation Grant and Installation Loan; Sabbatical Leave and Contact Visits; Superannuation and Medical Aid Schemes. For persons recruited from outside Zimbabwe-Rhodesia, unfurnished accommodation on or near the Campus and close to good junior and senior schools, is guaranteed for up to three years.

Appointments may be on permanent pensionable terms or for a fixed term of 1 or 2 years in the first instance. In the case of 1 or 2 year contracts a non-pensionable salary is payable on the above scales plus a 10% supplement.

At present, immigrants and persons on temporary contract, are exempted from military service for two years from the date of their arrival in Zimbabwe-Rhodesia.

Further particulars and details of application procedure may be obtained from the Association of Commonwealth Universities (Apts), 36 Gordon Square, London WC1H 0PF.

Closing date for the receipt of applications is 18 July 1979.

British subjects considering applying for posts in Rhodesia are urged to consult the Foreign and Commonwealth Office (telephone 01-233 8727) or their nearest British Consular Office. 2318(A)

# OVERSEAS DEVELOPMENT

KNOW-HOW-vital to developing countries

## Rice Agronomist

Tanzania

Required to work in Southern Tanzania with responsibility for executing a rice research programme. Will be stationed at Naliendele Agricultural Research Institute and will provide the main source of professional advice on rice production with priority being given to the areas selected for inclusion in the Tanzania/British Joint Programme. Will be assisted by a Field Officer and two Field Assistants provided by the Ministry of Agriculture and will directly supervise their work. Will also advise on a suitable staff training programme, including in service and overseas training. At least five years experience of irrigated rice production and experimentation required.

Appointment 2 tours of 1 year. Salary (UK taxable) in senior range above £10,000 pa plus tax-free overseas allowances in range £1,400 to £3,570 pa and £380 to £760 pa (Ref 331X)

*The post is wholly financed by the British Government under Britain's programme of aid to the developing countries. In addition to basic salary and overseas allowances other benefits normally include paid leave, free family passages, childrens education allowances and holiday visits, free accommodation and medical attention. Applicants should be citizens of the United Kingdom.*

*For full details and application form please apply, quoting reference stating post concerned, and giving details of age, qualifications and experience to:—*

Appointments Officer,  
OVERSEAS DEVELOPMENT ADMINISTRATION,  
Room 301, Eland House,  
Stag Place, London SW1E 5DH.

HELPING NATIONS HELP THEMSELVES

2341(A)

## UNIVERSITY OF KEELE

### DEPARTMENT OF GEOLOGY

#### Departmental Demonstratorships

Applications invited for two full-time posts of Demonstrator from 1st October 1979, for one year in first instance, to assist with teaching of all aspects of Geology at an elementary level together with advanced courses in fields specified below. Postgraduate and/or industrial experience and a current British driving licence would be advantageous.

Post (a) Demonstrator in mineralogy, igneous and metamorphic petrology and map work.

Post (b) Demonstrator whose major interest is in clastic or carbonate sedimentology.

Initial salary £3,775 on Grade 1B scale, with membership of the Universities Superannuation Scheme.

Further details and application forms from The Registrar, The University, Keele, Staffs., ST5 5BG, to whom application forms should be returned not later than Friday 6th July 1979. (Previous applicants are not required to re-apply.) 2278(A)

## UNIVERSITY OF DURHAM

### DEPARTMENT OF BOTANY

Applications are invited from candidates with biochemical experience for the post of Senior Experimental Officer tenable from 1 October 1979. Duties include both demonstrating and research plus responsibility for the operation of some physiological and biochemical equipment.

Salary on Range 1A £4,333 to £7,521 pa plus superannuation.

Applications (3 copies), naming three referees should be sent by 4 July to the Registrar and Secretary, Science Laboratories, South Road, Durham, DH1 3LE, from whom further particulars may be obtained. 2275(A)

## CSIRO AUSTRALIA

### Postdoctoral Research Fellow

#### Division of Mineral Chemistry

#### Port Melbourne Victoria

CSIRO has a broad charter for research into primary and secondary industry areas. The Organization has approximately 7,000 employees — 2,400 of whom are research and professional scientists — located in Divisions and Sections throughout Australia.

**GENERAL:** The Division conducts research in the fields of solid-state and surface chemistry, metallurgy and electrochemistry. The research program on high energy density batteries for traction applications is being expanded under sponsorship from the National Energy Research, Development and Demonstration Council.

**DUTIES:** To participate in a research program to develop nickel-zinc secondary batteries.

**QUALIFICATIONS:** A PhD or equivalent in a relevant area of chemistry or chemical engineering. Experience in electrochemistry or battery technology would be an advantage.

**SALARY:** Research Scientist A\$15,422 to A\$18,904 p.a.

**TENURE:** The appointment will be for 2½ years with a possibility of extension.

Applications IN DUPLICATE, stating full personal and professional details, the names and addresses of at least two professional referees, and QUOTING REFERENCE NUMBER 601/307 should reach:—

The Personnel Officer, Australian Scientific Liaison Office, Canberra House, 10-16 Maltravers Street, London WC2R 3EH, by 27th July, 1979.

Applications in USA and Canada should be sent to:— The Counsellor Scientific, Embassy of Australia, 1601 Massachusetts Avenue, N.W., Washington, D.C., 20036, U.S.A.

2352(A)

# Cardiovascular Pharmacologists

Applications are invited from experienced pharmacologists for the following positions which have arisen within the highly successful cardiovascular sections of our Pharmacology Department.

## 1. A Graduate or PH.D. Pharmacologist

is required to lead a small team of technicians developing continuous recording techniques in conscious animals, in order to study the haemodynamic effects of new drugs. The successful candidate will be a skilled practical worker and will have at least 3 years' experience of cardiovascular techniques, preferably in conscious animals. There will be scope for basic research in associated areas.

## 2. A Graduate or PH.D. Pharmacologist

is required to join an established team of graduates and technicians, whose immediate objective is the identification of novel mechanisms to further the development of new antihypertensive agents. The ideal applicant will have at least 2 years' postgraduate experience and a thorough knowledge of the cardiovascular and autonomic nervous systems. He or she must be able to work independently within a specific area of investigation.

These are challenging and rewarding positions, and the people appointed will be expected to make a substantial contribution towards the creative effort of the department.

We offer a competitive salary commensurate with experience, plus a Ware Allowance. The successful candidates will participate in a non-contributory pension and life assurance scheme, as well as bonus and productivity schemes. Other benefits include a subsidised canteen, a flourishing sports and social club and (where appropriate) assistance with relocation to this most attractive area of Hertfordshire.

Please write, or telephone, for an application form to: Dr. D.J. Humphreys, Personnel Officer, Glaxo Group Research (Ware) Ltd., Ware, Hertfordshire SG12 0DJ. Tel: Ware 3232 2362(A)

# Glaxo Group Research Ltd.

## PAISLEY COLLEGE

Due to the continuing expansion of its CNAA degree programme, Paisley College, a Scottish Central Institution, invites applications for the following post:—

## LECTURER IN BIO-CHEMISTRY Department of Biology

Applicants should have a good honours degree in Biochemistry and post-graduate research experience.

The successful candidate will have an interest in Pharmacology and will be involved in the teaching of Biochemistry at HNC, HND, BSc (Biology/Dietetics) and honours levels. In addition a contribution to the teaching of Pharmacology to HNC and BSc (Dietetics) is expected. Research is encouraged.

## SALARY SCALE Lecturer 'A' £4,422/£8,391.

Application forms and further particulars may be obtained from The Personnel Officer, Paisley College of Technology, High Street, Paisley (Tel No. 041 887 1241), to whom completed application forms should be returned within ten days of the appearance of this advertisement. 2306(A)

## UNIVERSITY OF CAMBRIDGE

### DEPARTMENT OF PHARMACOLOGY

Applications are invited for the office of  
UNIVERSITY LECTURER IN  
THE DEPARTMENT OF  
PHARMACOLOGY.

The initial appointment will be for three years from 1 October 1979 with the possibility of reappointment to the retiring age. The pensionable stipend for a University Lecturer will be on a scale of £5,850 rising by twelve annual increments to £9,000 a year with initial placing above the minimum where appropriate. There is no grade of Senior Lecturer. A grant is made towards removal expenses.

Candidates should send twelve copies of their application together with the names of not more than three referees to Mr G. R. Anderson, General Board Office, The Old Schools, Cambridge, CB2 1TT, from whom further information can be obtained, to arrive not later than 15 August 1979. 2292(A)

LABORATORY SCIENTIFIC OFFICER required for two years to join a research team investigating mammalian meiosis. HNC or equivalent qualification required. Applications should be sent to the Administrative Assistant, Paediatric Research Unit, The Prince Philip Research Laboratories, Guy's Tower, Guy's Hospital, London Bridge, SE1 9RT, as soon as possible. 2284(A)

## POSITION OPEN BIOMEDICAL MASS SPECTROSCOPIST (PhD)

wanted immediately. Duties include planning and execution of multiple research programs involving application of gas chromatographic mass spectrometric techniques to biomedical and environmental problems. Salary \$15,000/annum. Please send resumes to: The Oregon Graduate Center, 19600 NW Walker Road, Beaverton, OR 97005 Attn: Joanne Brink, Personnel Administrator AA/EEO. W193(A)

## MEDICAL RESEARCH COUNCIL RADIOBIOLOGY UNIT CYTOGENETICS

A vacancy exists for a scientist to work in a group investigating the effects of ionizing radiation upon chromosomes in a variety of cells and tissues.

Applicants should have a good honours degree, and at least 3 years post-graduate research experience. They should be conversant with modern cytogenetic techniques and some knowledge of tissue culture is desirable.

Usual Medical Research Council conditions of service. Salary according to age and qualifications. Applications in writing to: The Administrator, M.R.C., Radiobiology Unit, Harwell, Didcot, OXON OX11 0RD, quoting reference JRKS/1. 2 2 8 0 (A)

## UNIVERSITY COLLEGE CARDIFF

Applications are invited for the post of  
POST DOCTORAL  
RESEARCH ASSISTANT

in the DEPARTMENT OF CHEMISTRY (Inorganic). Research would be in co-ordination chemistry, probably in one of: Raman spectroscopy, crystallography of stereo-chemistry, reactions of ligands and mechanisms, biological aspects. Some teaching duties will be required. Salary range: £4,232 to £5,321 p.a. Duties to commence as soon as possible.

Applications (2 copies), together with the names and addresses of two referees should be forwarded to the Vice-Principal (Administration) and Registrar, University College PO Box 78, Cardiff CF1 1XL. Further details available from Professor Gillard, Department of Chemistry (Inorganic), Cardiff 44211 Ext. 2173. Closing date 31st July 1979. Reference 1835. 2271(A)

## NATIONAL VEGETABLE RESEARCH STATION ASSISTANT NEMATOLOGIST

A SCIENTIFIC OFFICER is required to assist with work on the nematode pests of vegetables.

The appointment will be in the grade of Scientific Officer salary scale £2,839 per annum rising by annual increments to £4,415. (Salary review 1 April 1979 pending).

Minimum qualifications required is a degree or equivalent in Biological Science and experience in Nematology would be an advantage.

Non-contributory employers' additional pension scheme.

Full particulars and application form (to be returned by 18 July 1979) from the Secretary, National Vegetable Research Station, Wellesbourne, Warwick CV35 9EF. 2316(A)

**PORTSMOUTH  
POLYTECHNIC  
BIOCHEMISTRY/  
MOLECULAR BIOLOGY**

A Lecturer II/Senior Lecturer is required to undertake teaching and research duties in this field.

The person appointed will take overall responsibility for the teaching of biochemistry and molecular biology within the multi-disciplinary Biomolecular Science BSc. course (3 years full-time, Honours) and will personally teach a major proportion of the material.

Facilities for research are extensive. The existing research group emphasises a multi-disciplinary approach to the structure and function of chromatin and is supported by SRC and CRC.

Salary scale: £4,101 to £6,051 (efficiency bar) to £7,572 per annum (under review).

Further details and application forms from the Staff Officer, Portsmouth Polytechnic, Alexandra House, Museum Road, Portsmouth, PO1 2QQ, to whom completed applications should be returned by 20th July 1979, quoting ref. no. S56.

2268(A)

**CHELSEA HOSPITAL FOR  
WOMEN**

Dovehouse Street, London SW3

The Semiology Laboratory at the Chelsea Hospital for Women require a

**MEDICAL LABORATORY  
SCIENTIFIC OFFICER**

with experience in bacteriology or immunology.

The work involves investigation of subfertile couples, seminal analysis, freezing sperm and the detection of sperm antibodies in male and female by macro and micro techniques. Experience with tissue typing would be useful.

Further information and application form obtainable from The Administrative Assistant, Queen Charlotte's Maternity Hospital, Goldhawk Road, London W6 0XG. Tel: 01-748 4666 ext 204.

2327(A)

**UNIVERSITY OF BRISTOL**

Department of Biochemistry

**POSTDOCTORAL  
RESEARCH ASSISTANT**

Applications are invited for a postdoctoral research assistant to join a group investigating the hormonal regulation of glutamine metabolism in liver. The appointment is for a maximum of three years and is funded by the Medical Research Council. Salary is within the University Range 1A — £4,232 to £7,145 per annum (scale subject to revision from 1st October, 1979). Some experience in protein separations techniques would be advantageous.

Applications, enclosing a curriculum vitae and the names and addresses of two referees should be sent to Dr. J. D. McGivan, Department of Biochemistry, Medical School, University Walk, Bristol BS8 1TD before July 15th, 1979.

2296(A)

**ROYAL FREE HOSPITAL  
SCHOOL OF MEDICINE  
University of London**

Department of Biochemistry and Chemistry

**POSTDOCTORAL  
RESEARCH ASSISTANT**

Bio-physical chemist required to join research group working on membrane structure and function. Experience of surface techniques or material science would be a particular advantage. The post is tenable for up to 3 years, supported by the Science Research Council. Initial salary within range £4,261 to £4,805 plus £502 London allowance.

Applications, naming two referees, to the School Secretary, R.F.H.S.M., 8 Hunter Street, London, WC1N 1BP as soon as possible.

2276(A)

**european space agency**

The European Space Agency has the following vacancies in the Space Science Department at its Technological Centre in Noordwijk, the Netherlands:

**Astronomers**

Applications are invited from U.V. and optical astronomers. Applicants should either have a strong background in advanced detector systems, with experience in their application to astronomy, or they should be observers with an extensive astrophysical background and experience in using advanced space and ground based instruments. Duties will include scientific project work associated with possible future and on-going space astronomy projects together with joint research using IUE and an advanced photon counting system.

**Space Plasma Physicists**

Applications are invited from physicists with experience in particle, field and wave measurements in a magnetized plasma — in space or in the laboratory. Interested candidates should have a background in experimental techniques in this field and preferably also have experience with data analysis. Duties will partly be scientific project work related to studies and on-going projects where elements of space plasma physics are included, and partly research related to experiment development and analysis of data from on-going projects such as GEOS and ISEE.

Applications for these posts should be sent, as soon as possible, to the Head of Personnel, ESTEC, Zwarteweg 62, Postbus 299, AG 2000, Noordwijk, the Netherlands.

W189(A)

**UNIVERSITY OF EXETER  
LECTURER IN  
COMPUTER SCIENCE**

Applications are invited for a lectureship in the Department of Computer Science, tenable from 1 October 1979.

Candidates should be qualified persons working in any area of computer science. Specializations which are of particular interest, but which are not intended to make up an exhaustive list, are: data-base computation and theory; artificial intelligence; computer architecture and systems; theory of programming languages and semantics; operating systems; distributed computing and networks.

Commencing salary will be within the range £4,232 to £6,368 pa (under review) on the scale £4,232 to £8452 pa (under review). The post is subject to a probationary period not exceeding three years with the prospects of permanency thereafter.

Further particulars may be obtained from Miss Doreen Watson, University of Exeter, Northcote House, Exeter, EX4 4QJ, to whom applications (8 copies) should be forwarded by 23 July 1979. Please quote reference No 3216.

People who have applied for a similar post earlier this year will be automatically considered for this present post.

Further information may be obtained from Professor J. A. Campbell, Department of Computer Science (Ext. 216).

2313(A)

**UNIVERSITY COLLEGE GALWAY, IRELAND**

**DEPARTMENT OF PHYSICS**

Arising out of the introduction of an optional honours physics degree in applied physics and electronics, an initial appointment in one of the following specialities is to be made.

- 1) Physicist or Electronic Engineer with broad experience in hardware and software computing or
- 2) Electronic/Electrical Engineer or Physicist with experience in control systems and/or micro-electronics. Industrial experience would be an advantage.

The salary will be in the range £5,000 to £8,000 p.a.

The appointment will be for twelve months and will not be renewable. The college however, hopes to advertise several appointments in this area in 1980 at either Junior Lecturer (£4,852 to £6,706, under review) or Lecturer (£7,220 to £9,530, under review).

For further information please contact the Registrar (Telephone Galway 7611, ext. 192, telex 8823). Closing date for receipt of applications is July 6th 1979.

2339(A)

## Director of Biology Ware, Herts.

Applications are invited from experienced biochemists or pharmacologists to be responsible to the Managing Director for the scientific standards of work carried out in the Pharmacology and Biochemistry Departments. This includes testing and evaluating research compounds as well as basic research.

In addition, the position involves directing multi-disciplinary research projects, and there is considerable interaction with senior people in related disciplines. Consequently, sufficient knowledge of other areas is necessary to enable the successful applicant to make a full contribution to the research and development activity.

Candidates must have extensive industrial experience of pharmaceutical R&D in a pertinent biological discipline. It is unlikely that people below the age of 35 will have the required knowledge or experience for the position.

The salary for this senior position is negotiable and a company car will be provided. Our modern, well-equipped laboratories are set in pleasant surroundings in Hertfordshire, and relocation assistance will be available if appropriate. Other benefits include non-contributory pension scheme and the opportunity to participate in Group profitability.

Please forward your curriculum vitae, in confidence, to: Ian Collins, Ph.D., Personnel Manager, Glaxo Group Research Ltd., Ware, Herts. SG12 0DJ. 2329(A)

# Glaxo Group Research Ltd.

## UNIVERSITY OF MANCHESTER DEPARTMENT OF MEDICAL BIOCHEMISTRY POST-DOCTORAL RESEARCH ASSOCIATE

Applications invited for this post (available up to three years from October) to work with Dr C. A. Shuttleworth and Dr M. E. Grant on "The Role of Non-Collagenous proteins in the Periodontal Ligaments". Some experience in the fields of connective tissue biochemistry, protein chemistry, tissue culture or embryogenesis would be an advantage. Starting salary in the range £4,333 to £4,910 p.a. Superannuation. Applications (three copies) including curriculum vitae and the names of two referees should be sent to Dr C. A. Shuttleworth, Department of Medical Biochemistry, University of Manchester Medical School, Manchester M13 9PT as soon as possible. 2312(A)

## UNIVERSITY OF CAMBRIDGE ZOOLOGY DEPARTMENT

### Research Assistant

To collaborate with Dr. M. Burrows on the morphology or physiology of local interneurons in insects. Experience of light or electron microscopical techniques, or of neuro-physiological techniques an advantage. The appointment, to begin as soon as possible, is short term, approx. 18 months. Salary according to age and experience to £4776 max. (under review). Applications (c.v. and names of two referees) to Dr. M. Burrows, Zoology Department, Downing Street, Cambridge CB2 3EJ by 31st July, 1979. 2364(A)

## MANCHESTER AREA HEALTH AUTHORITY (T) CENTRAL DISTRICT SENIOR CYTOGENETICIST

The expanding Regional Laboratory which deals with blood, fibroblast and amniotic material is located within the University Department of Medical Genetics. This Department also provides Genetic Counselling and HLA typing services and there is excellent clinical liaison.

Only candidates holding or eligible for an NHS Senior Cytogeneticist post and having extensive experience of Medical Cytogenetics should apply.

Applications with full details of experience and qualifications and the names of two referees should be sent to Dr Rodney Harris, Department of Medical Genetics, St. Mary's Hospital, Manchester M13 0JH. 2308(A)

## UNIVERSITY COLLEGE LONDON RESEARCH ASSISTANT

Research Assistant required to assist physical anthropology staff in research and teaching duties. The post will also involve curation of the physical anthropology teaching material collection, routine computer/clerical tasks and assistance in specific research projects. A first degree in a biological science and an interest in physical anthropology/human biology is essential. The successful candidate may be given an opportunity to conduct research leading to a higher degree. Tenable from October 1979. Salary range £3,775 to £4,910 plus £502 London allowance. Applications to Assistant Secretary (Personnel) University College London, Gower St, London WC1E 6BT. 2320(A)

## UNIVERSITY OF LIVERPOOL BIOENGINEERING AND MEDICAL PHYSICS UNIT RESEARCH ASSISTANT

Applications are invited for the post of Research Assistant/Senior Research Assistant to work on a research project concerned with the development of an artificial blood vessel.

The project has been running for three years and has led to a prototype vessel which is at present undergoing thorough evaluation, leading eventually to commercial exploitation.

The research assistant will be involved in the application and development of small scale production and testing apparatus, as well as being innovative in making improvements necessary for future generations of prosthesis. He/she will be expected to utilize his/her own specialities and interests in the research and development of the improved product.

The post is most suitable for someone with a degree in a related physical science, an interest in bioengineering and possibly research experience. Any queries regarding the post should be made to Mr R. Clarke, 051-709-6022, ext. 2292.

The initial salary will be on the scale £3,689-£5,321 p.a., or £4,232-£4,776 p.a., for candidates with a Ph.D.

Applications, together with the names of three referees, should be received not later than 20th July, 1979 by the Registrar, The University, P.O. Box 147, Liverpool, L69 3BX. Quote Ref: RV/673. 2357(A)

## UNIVERSITY OF SALFORD DEPARTMENT OF CHEMISTRY AND APPLIED CHEMISTRY LECTURER IN ORGANIC CHEMISTRY

Applications are invited for the above post from well qualified candidates with teaching and research interests in the field of pure and applied chemistry. The post is available from 1 October, 1979.

Salary scale £4,232 to £8,452 p.a. USS benefits.

Application forms and further particulars are available from the Registrar, University of Salford, Salford M5 4WT (tel: 061-736 5843 ext. 215) to whom completed applications should be returned by 27 July, 1979, quoting reference no: CH/260/N. Informal enquiries may be made to Professor H. Suschitzky. 2326(A)

## UNIVERSITY OF LIVERPOOL

### Department of Oceanography Senior Research Assistant/ Research Associate

Applications are invited for the post of Senior Research Assistant/Research Associate to investigate the fine structure and microstructure of the upper oceanic layers. Candidates should possess a PhD with preferably some experience in numerical modelling. The project is sponsored for three years by the Ministry of Defence at an initial salary within the range £4,776 to £6,368 per annum, depending on age and experience.

Applications, together with the names of three referees should be received not later than 1st August 1979, by the Registrar, The University, PO Box 147, Liverpool L69 3BX, from whom further particulars may be obtained. Quote Ref: RV/671. 2355(A)

## ODENSE UNIVERSITY DENMARK

A new position as Professor in Photosynthesis has been created in the Institute of Biochemistry, and is available for occupation as soon as possible.

It is desired to appoint a person whose research activities are experimental investigations of the functions of the photosynthetic membrane systems in eukaryotes and/or prokaryotes. A part of the current research in the Institute is concerned with electron transport in respiratory and photosynthetic systems, and the Institute is well equipped with special apparatus for this type of work.

The successful applicant will be expected to participate in the teaching programme of the Institute, which includes elementary courses common to science and medical students, advanced courses for advanced students and supervision of advanced project work.

Further information is obtainable from Institute of Biochemistry, Odense University, telephone (09) 15 86 00, ext. 2441.

The application should contain information about the candidate's teaching experience. It is expected that the successful applicant will eventually be able to teach in Danish.

The employment field covers the Ministry of Education and the institutions under it. The wage frame is 37, and the salary amounts to Danish Kroner 230.520,24 a year inclusive of bonuses as per the October 1, 1978.

A professional selection committee will discuss the applications and their recommendation will be sent out to all applicants in its complete form.

Application in 5 copies, marked "Position No. 745", enclosing curriculum vitae and documentation for professional and pedagogical activities must be made to the Queen and sent together with all enclosures also in 5 copies to: Journalkontoret, Odense University, Campusvej 55, DK 5230 Odense M, Denmark, so that we will receive it by October 1, 1979 at the latest. W173(A)

# AGRICULTURAL RESEARCH COUNCIL

## UNIT OF NITROGEN FIXATION

A vacancy has arisen for a Scientific Officer to work in our Chemistry Department.

The work will involve the development of catalytic systems for the reduction of molecular nitrogen. The successful applicant will work with a minimum of supervision and after consultation will be required to design new experiments. Applicants should have a Degree in Chemistry.

Salary in a scale £2,839 to £4,415 (under review from 1 April 1979) depending upon qualifications and experience. Non contributory superannuation scheme.

Applications in writing to the Secretary at the ARC Unit of Nitrogen Fixation, University of Sussex, Brighton BN1 9RQ with curriculum vitae and the names of three referees. Closing date 12/7/79.

2324(A)

# REPRODUCTIVE BIOLOGIST

## MCGILL UNIVERSITY Montreal

### DIVISION OF REPRODUCTIVE BIOLOGY DEPARTMENT OF OBSTETRICS AND GYNECOLOGY

invites applications for an Assistant Professor position. Candidates must hold Ph.D. or M.D. degrees, have at least two years of post-doctoral training and have documented research interests in some aspect of reproductive biology (e.g., neuro-endocrinology, gonadal function, fetal growth, hormone receptors, etc). Candidates will be expected to establish their own research group and to compete for outside grant support. Personal salary and starting date negotiable; teaching commitments commensurate with experience. Closing date for applications: September 1, 1979. Send curriculum vitae, list of publications and three letters of reference to: Dr K. B. Ruf, Research Laboratories, Women's Pavilion, Royal Victoria Hospital, 687 Pine Avenue West, Montreal H3A 1A1, Canada.

W196(A)

# THE UNIVERSITY OF TORONTO ASSISTANT PROFESSORS IN BIOCHEMISTRY

Applications are invited for two positions of Assistant Professor in the Department of Biochemistry (one to be located in the Playfair Neurosciences Unit) to take effect from July 1, 1980. Both appointees will be on a two-year contract with possibility of renewal for a further three years. The successful applicants will be required to take part in the teaching programs of the Department and to develop a research program. The appointment to the Playfair Unit will be made in the area of membrane or receptor biochemistry; the other position has no field restrictions. The Department is involved in teaching Biochemistry to undergraduates in the Faculties of Medicine, Dentistry, Arts and Science, and Nursing, as well as graduate students. The minimum salary for both positions will be \$18,000.00.

Applicants with suitable qualifications should send a curriculum vitae and the names and addresses of three referees to: Chairman of the Search Committee, Department of Biochemistry, University of Toronto, Toronto, Canada, M5S 1A8, to reach him not later than September 30, 1979.

W182(A)

# UNIVERSITY OF LEEDS Grade 5 Technician

An experienced Laboratory Technician is required immediately for the Department of Obstetrics and Gynaecology (Leeds Maternity Hospital). The technical work is concerned mainly with immunological aspects of human reproduction and requires knowledge of immunologic methodologies. The holder of this post is also responsible for the routine supervision of the laboratory, including ordering and checking supplies and equipment. Applicants should possess an HNC or equivalent qualifications and have had about seven years relevant experience. Salary on the scale £3,474 to £4,056 p.a. Applications should be made in writing to Professor J. S. Scott, Department of Obstetrics and Gynaecology (Leeds Maternity Hospital) University of Leeds, 17 Springfield Mount, Leeds LS2 9NG.

2333(A)

# EAST BIRMINGHAM HOSPITAL REGIONAL CYTOGENETICS LABORATORY

Applications are invited for the post of Scientific Officer. Experience in medical cytogenetics including cell tissue culture desirable but not essential. Salary range depending upon experience and qualifications £2,991 to £4,899 per annum.

Application forms and job description obtainable from Regional Cytogenetics Laboratory, East Birmingham Hospital, Bordesley Green East, Birmingham B9 5ST. Tel. 021 772 4311 ext. 4354.

2335(A)

# DEPARTMENT OF MORPHOLOGY UNIVERSITY OF GENEVA MEDICAL SCHOOL Geneva, Switzerland

invites applications for a position of

## RESEARCH ASSOCIATE

in Developmental Biology

Candidates should be M.D. or Ph.D. with experience of teaching embryology to medical students and be able to set up an active research unit in the Department. Ability to teach in French is mandatory. Salary, before income tax, starts at Sfr. 57,000 per annum. Send complete résumé to: Dr L. Orci, Chairman, Department of Morphology, Medical School, rue Ecole de Médecine, 1211 Geneva 4, Switzerland.

W197(A)

# FORINTEK CANADA CORPORATION WESTERN FOREST PRODUCTS LABORATORY

Wood Biodeterioration and Protection — a PROFESSIONAL MYCOLOGIST is required immediately to join a highly qualified research team in Vancouver, Canada. Applicants should have a Ph.D. plus several years experience with wood-inhabiting fungi. A knowledge of decay problems in buildings would be desirable. A demonstrated ability to do applied research and to communicate both to industry and the general public will be required. Salary negotiable from 25,000 dollars, depending on qualifications and experience. Applications, with two references, to Dr R. S. Smith, Forintek Canada Corp., Western Forest Products Laboratory, 6620 N.W. Marine Drive, Vancouver, B.C., Canada V6T 1X2.

W199(A)

# NURSING PRACTICE RESEARCH UNIT

## NORTHWICK PARK HOSPITAL & CLINICAL RESEARCH CENTRE

# Project Leader

Salary in the range £3,883 to £6,555 p.a. plus £502 UGC London Weighting Allowance

(Starting salary will depend upon qualifications and experience.)

Applications are invited for the new post of Project Leader in the developing national Nursing Practice Research Unit which has been established by the Department of Health and Social Security at Northwick Park Hospital. Applicants should be science graduates, with suitable research experience, and preferably hold a nursing qualification. The appointment is initially for a three-year period.

The Project Leader will primarily be responsible for developing a programme of research into the treatment of Pressure Sores. In addition, he/she will contribute to the broad development of the Unit as a national centre for research into clinical nursing practice. This will include devising methods and techniques for clinical nursing research and assisting with the training of nurses and others who are interested in nursing practice research. The Unit will also act as a centre for the collation and dissemination of information about research into nursing practice.

Interested applicants are welcome to contact Dr. Rosemary Crow, Director, Nursing Practice Research Unit, for informal discussion before submission of application. Telephone 01 864 5311 ext. 2881.

Further particulars and application forms can be obtained from the Area Personnel Department, Brent and Harrow Area Health Authority, Signal House, Lyon Road, Harrow, Middlesex. Telephone 01 863 9111 ext. 41.

Closing date for applications is 20th July, 1979.

2349(A)

# THE MAX-PLANCK-INSTITUT FÜR ZÜCHTUNGSFORSCHUNG

invites applications for the post of

## MOLECULAR GENETICIST

to take part in a research programme aimed at elucidating the genetics of the interactions between plant and bacterium in symbiotic nitrogen fixation. The project will involve investigation of legume and *Rhizobium* genomes in controlling specificity in the symbiosis. The successful applicant will have had post-doctoral experience with plasmid isolation and characterization.

Two types of appointment are possible: for a fixed period of up to five years or for an indefinite period. Both carry remuneration on the German BAT scales 2a to 1a. Applicants should send a curriculum vitae and the names and addresses of three referees to

J. Schell, Director  
Max-Planck-Institut für Züchtungsforschung  
5000 Köln 30 (Vogelsang)  
Federal Republic of Germany

before October 1, 1979.

W191(A)

Brent & Harrow Area Health Authority Brent Health District  
Central Middlesex Hospital

## Medical Laboratory Scientific Officer

CLINICAL INVESTIGATION DEPARTMENT

We require either a qualified M.L.S.O. or a B.Sc. Graduate in Medical Sciences to fill the above post shortly to become vacant. Duties cover basic laboratory work specialising in Radio Immuno Assay techniques. Previous experience in this field or within a Biochemistry orientated discipline would be preferable.

**Hours:** 38 per week  
**Salary:** Qualified M.L.S.O. £3,615 to £5,034 inclusive.

**Please contact** Mrs. Janice Andrews, Personnel Department, Central Middlesex Hospital, Acton Lane, London NW10 7NS Telephone: 01-965 5733 ext. 656. 2342(A)

REQUIRED BY THE  
FOOD AND AGRICULTURE  
ORGANIZATION OF THE  
UNITED NATIONS, ROME, ITALY

## CROP PROTECTION SPECIALISTS

(Phytopathologists, Entomologists, Weed Scientists)

to be stationed in Sahelian countries, serving in a large-scale project on Integrated Pest Management for Basic Food Crops implemented with the assistance of FAO by the Inter-States Permanent Committee for Drought Control in the Sahel (CILSS).

**ESSENTIALS:** Ph.D. in Plant Protection Sciences. At least 7 years of post-graduate experience in pest management. Good working knowledge of English or French.

**SALARY:** dependent on qualifications/seniority, net tax-free including the usual International Civil Service allowances. Please send detailed curriculum vitae quoting "TF/RAF/128(USA)-comm." to Mr T. Eshetu, Manpower Planning, AGO, FAO, Via delle Terme di Caracalla, 00100 Rome, Italy. W184(A)

### UNIVERSITY OF EXETER LECTURER IN COMPUTER SCIENCE

Applications are invited for a lectureship in the Department of Computer Science, tenable from 1 October 1979.

Candidates should be qualified persons working in any area of computer science. Specializations which are of particular interest, but which are not intended to make up an exhaustive list, are: data-base computation and theory; artificial intelligence; computer architecture and systems; theory of programming languages and semantics; operating systems; distributed computing and networks.

Commencing salary will be within the range £4,232 to £5,048 pa (under review) on the scale £4,232 to £8452 pa (under review). The post is subject to a probationary period not exceeding three years with the prospects of permanency thereafter.

Further particulars may be obtained from Miss Doreen Watson, University of Exeter, Northcote House, Exeter, EX4 4QJ, to whom applications (8 copies) should be forwarded by 23 July 1979. Please quote reference No 3216.

People who have applied for a similar post earlier this year will be automatically considered for this present post.

Further information may be obtained from Professor J. A. Campbell, Department of Computer Science (Ext. 216). 2313(A)

### UNIVERSITY COLLEGE LONDON

#### DEPARTMENT OF CHEMISTRY

Applications are invited for an SRC Post-Doctoral Assistant available for one year from October 1st 1979. The successful applicant will investigate the ionisation potentials of organic molecules and the appearance potentials of fragment ions with the object of accurately determining the heats of formation of such ions. The apparatus consists of a double hemisphere electron energy selector, a quadrupole mass filter and ion counting equipment. The instrument is controlled by a PDP8 computer. Salary in range £4,261 to £4,805 plus £502 London allowance; USS. Applications consisting of curriculum vitae and names and addresses of two referees should be sent as soon as possible to Professor Maccoll, Dept. of Chemistry, University College London, 20 Gordon St, London WC1H 0AJ. 2273(A)

### UNIVERSITY OF READING POSTDOCTORAL RESEARCH ASSISTANT

GEOCHEMIST required as soon as possible, for a fixed term to be determined, for research on volatiles in magmas and minerals. The project funded for three years by the NERC is supervised by Professor D. K. Bailey and is to apply new techniques to the extraction and analysis of gases from glassy lavas, and volatile-bearing minerals, with the aim of elucidating igneous and ore-forming processes. Applicants should already have a doctorate (or be submitting a thesis) in geochemistry. Experience in experimental petrology, mass spectrometry or gas chromatography will be an advantage. Salary £4,232 p.a. (under review) plus USS superannuation. Apply quoting Ref. MN44A with curriculum vitae and the names of two referees to Assistant Bursar (Personnel), University of Reading, Whiteknights, Reading RG6 2AH. 2269(A)

### STUDENTSHIPS

## ROBERT GORDON'S INSTITUTE OF TECHNOLOGY, ABERDEEN

### SCHOOL OF PHARMACY

### RESEARCH STUDENTSHIP

Honours graduate, or student about to graduate, in Pharmacology, Pharmacy or related sciences for SRC (Case) Studentship in conjunction with Wellcome Research Laboratories to study intravascular platelet aggregation. CNA higher degree registration encouraged.

Applications or enquiries to:

Head of School of Pharmacy,  
Robert Gordon's Institute of Technology,  
Schoolhill,  
Aberdeen.  
AB9 1FR

2293(F)

## STUDENTSHIPS—continued

**THE UNIVERSITY OF SHEFFIELD  
DEPARTMENT OF METALLURGY  
SRC CASE STUDENTSHIPS**

Applications are invited from men and women for *ten* SRC/CASE studentships tenable from 1 October 1979 for research in the following fields:

- in co-operation with Delta Materials Research Limited, Ipswich. "Rheocasting of copper-based alloys"
- in co-operation with Firth Vickers Foundry Limited, Sheffield. "Processing and properties of centrispun castings"
- in co-operation with Wilkinson Match Limited, Slough. "Formation and properties of some high-strength glassy alloys"
- in co-operation with British Aluminium Company Limited, Gerrards Cross. "Stability of solid solutions extended by rapid freezing"
- in co-operation with Spring Research & Manufacturer's Association, Sheffield. "Effect of hot prestressing on reduction in spring relaxation"
- in co-operation with GKN Group Technological Centre, Wolverhampton. "The influence of texture on fatigue behaviour of steels"
- in co-operation with Johnson Matthey Research Centre, Reading. "High conductivity alloys produced by rapid solidification"
- in co-operation with CEGB Marchwood Laboratories, Southampton. "Creep damage at welds under complex stress"
- in co-operation with CEGB Scientific Services Division, Gravesend. "Void assessment in materials with changing structure"
- in co-operation with BSC Scunthorpe. "Mineralogy of sinters made from mixtures of home and imported ore"

Applicants with or expecting good Honours degrees in metallurgy, materials science or related fields should write to Professor G. J. Davies, Department of Metallurgy, University of Sheffield, Sheffield S1 3JD. Quote ref: R 321/G 2303(F)

**UNIVERSITY OF READING  
Department of Physiology & Biochemistry  
SRC STUDENTSHIP**

A three-year SRC Studentship is available from October 1979 to study the neurophysiology and neurochemistry of hypothalamic regulation of luteinising hormone release in the domestic fowl. A good honours degree will be required.

Applicants should send a curriculum vitae and names and addresses of two referees to Dr. R. T. Gladwell, from whom further details can be obtained (0734-85123, extension 7640).

**SRC-CASE Studentships in collaboration with the  
National Institute for Research in Dairying at Reading**

1. A three-year Studentship is available from October 1979 to study the hormonal control of lactation in ruminants. The project will include culture techniques to study biochemical changes during mammary differentiation using samples obtained from ruminants. A good Honours degree in biochemistry of related subjects will be required. The supervisors will be Professor R. Dils (University) and Dr. I. Forsyth (NIRD).

Applications, including curriculum vitae and names and addresses of two referees, should be sent as soon as possible to Professor Dils (0734-85123, extension 7600) or to Dr. Forsyth (0734-883103, extension 281) from whom further details can be obtained.

2. A three-year Studentship is available from October 1979 to study nutrient binding factors in mammary gland and milk. The project will involve the isolation, characterisation and biosynthesis of binding proteins for vitamin B<sub>12</sub>, folate and fatty acids. A good Honours degree in biochemistry or related subjects will be required. The supervisors will be Professor R. Dils (University) and Dr. M. Gurr (NIRD).

Applications, including curriculum vitae and names and addresses of two referees, should be sent as soon as possible to Professor Dils (0734-85123, extension 7600) or to Dr. Gurr (0734-85123, extension 260) from whom further details can be obtained. 2305(F)

**THE UNIVERSITY OF LEEDS  
DEPARTMENT OF PHYSICS**
**SRC STUDENTSHIP IN  
PHYSICS**

Applications are invited from persons holding, or expecting to obtain, a Class I or II (i) Honours degree in Physics for a SRC studentship leading to the degree of PhD in the above Department. The successful candidate will join an active group of polymer physicists working under the direction of Professor I. M. Ward.

Applications with curriculum vitae and the names and addresses of two referees should be sent to Professor G. J. Morgan, Department of Physics, University of Leeds, Leeds LS2 9JT, from whom further details may be obtained. 2302(F)

**THE UNIVERSITY OF  
LEEDS  
DEPARTMENT OF  
PLANT SCIENCES**

Applications are invited from persons who have, or expect to obtain, a first or upper second class honours degree (the course work for which has included the advanced study of plant pathology) for an SRC CASE studentship under the supervision of Dr Alec Carr of the Welsh Plant Breeding Institute and Mr Tom Preece of the University of Leeds. The project is concerned with resistance to *Xanthomonas graminis* infection in grasses.

Applications, with the names of two referees, should be sent to Mr T. F. Preece, Agriculture Building, The University of Leeds, Leeds LS2 9JT, by 1 August 1979. 2304(F)

**UNIVERSITY OF  
NOTTINGHAM MEDICAL  
SCHOOL  
RESEARCH STUDENTSHIP  
IN MICROBIOLOGY**

Applications are invited for a Research Studentship in Microbiology leading to the degree of PhD for work on the continuous monitoring of the action of antibiotics on dense bacterial cultures.

Applications with the names and addresses of two referees to Professor F. O'Grady, Department of Microbiology, University Hospital, Queen's Medical Centre, Nottingham NG7 2UH. 2291(F)

**UNIVERSITY OF  
ST ANDREWS**
**Department of Biochemistry  
and Microbiology  
MSc Studentship in  
Biochemistry**

Applications are invited for a MSc studentship financed by the Mental Health Foundation. The project will involve *in vivo* and *in vitro* studies on the mode of action of certain sulphur-containing compounds on pyridoxal phosphate-dependent enzymes of the GABA pathway in mammalian brain.

The one year studentship (with the possibility of a further two years' extension) will commence as soon as possible after 1st October, 1979. Candidates should hold, or expect to obtain in 1979, at least an upper second class honours degree in Biochemistry or a related subject.

Applications, together with the names and addresses of two referees, should be sent to—Dr R. Griffiths, Department of Biochemistry and Microbiology, University of St Andrews, Irvine Building, North Street, St Andrews, Fife. 2287(F)

**UNIVERSITY OF READING  
DEPARTMENT OF BOTANY  
SRC (CASE) STUDENTSHIP**

Applications are invited from good honours graduates in Plant Sciences for a studentship (in collaboration with the Glasshouse Crops Research Institute, Littlehampton) to investigate the properties of the plant photoreceptor, *phytochrome*, in green plant tissues.

Further information is obtainable from Dr. C. B. Johnson, Botany Department, Reading University, Whiteknights, Reading RG6 2AS, to whom applications should be sent before 13 July 1979. 2270(F)

**UNIVERSITY OF  
NEWCASTLE UPON TYNE  
DEPARTMENT OF NEUROLOGY**

A Postgraduate Research Studentship is available for three years from October 1st, 1979 at the Regional Neurological Centre. The work will be concerned with the enzymology of protein breakdown in muscle. There is a large unit studying various aspects of muscle diseases at the Regional Neurological Centre. Applicants should have or expect to obtain a good Honours degree with biochemistry or chemistry as a major subject, and the successful candidate will register for a PhD degree. Remuneration will be the same as that of postgraduate students supported by the Medical Research Council.

Applications, including the names and addresses of two referees should be sent, as soon as possible to Dr R. J. T. Pennington, Neurochemistry Department, Regional Neurological Centre, General Hospital, Newcastle upon Tyne NE4 6BE. (0632-738811.) 2343(F)

**SCOTT POLAR  
RESEARCH INSTITUTE  
(University of Cambridge)  
NERC Studentship**

Applicants with strong background in mathematics or physical sciences interested in interpretation of geophysical data are invited to study "Ice Sheet Dynamics derived from radio echo sounding and other data". The Institute's collection of radio echo sounding data from Antarctica built up over the past twelve years provides an outstanding opportunity for testing existing glaciological theory and developing new ideas to replace concepts shown to be inadequate.

Contact the Director, Telephone Cambridge 66499 ext 464 or write sending details. 2354(F)

**THE UNIVERSITY COLLEGE  
OF WALES  
ABERYSTWYTH  
DEPARTMENT OF ZOOLOGY  
SRC RESEARCH  
STUDENTSHIP**

Applications are invited from good Honours graduates in the biological sciences for a PhD research studentship funded by the Science Research Council. The applicant must have interests centred in research areas in cell and developmental biology, immunology, parasitology, animal physiology, or behaviour.

The studentship is tenable for three years starting October 1, 1979. Application, including a full curriculum vitae and the names of two referees, should be sent to Professor

B M Jones, Department of Zoology, University College of Wales, Aberystwyth, Dyfed, SW23 3DA. Requests for further information should be made to the Secretary at the same address. 2331(F)

## STUDENTSHIPS—continued

### THE UNIVERSITY COLLEGE OF WALES ABERYSTWYTH

**DEPARTMENT OF PHYSICS**  
Applications are invited for postgraduate work in the Department of Physics for Session 1979-80. The Science Research Council is prepared to offer to suitable candidates a limited number of Research Studentships for ionosphere and space research and studies of atomic collisions in plasmas, shock and detonation waves and the flow of non-Newtonian fluids.

Applications are also invited for one-year SRC Advanced Course Studentships for an MSc course on the Physics of the Upper Atmosphere.

Applications to Professor, Sir Granville Beynon, CBE, FRS, Department of Physics, University College of Wales, Aberystwyth, 2334(F)

### SCHOOL OF PHYSICS UNIVERSITY OF NEWCASTLE UPON TYNE RESEARCH STUDENTSHIPS IN GEOPHYSICS AND PLANETARY PHYSICS

PhD studentships are available for graduates with First or Upper Second Class Honours in either: Physics; Geophysics; Astronomy; Geology; Chemistry or Mathematics.

Current research interests are: Evolution of Planets; Fluid Dynamics; Geochronology; Geomagnetism; Geophysical Electronic Instrumentation; High Pressure Geophysics; History of Earth's Rotation; Palaeomagnetism; Plate Tectonics; Rift Systems; Rock and Mineral Magnetism; Study of Lunar Samples; Submarine Cable Currents.

For further particulars, please write as soon as possible, giving personal details, to Mr J. M. Walmsley, Administrative Assistant, School of Physics, The University, Newcastle upon Tyne NE1 7RU. 2351(F)

### Department of Paramedical Sciences

### Chemotherapy Research Unit

Applications are invited from graduates in biochemistry and/or microbiology for an SRC-CASE studentship to investigate electron transport mechanisms in the protozoan *Trichomonas vaginalis*, in conjunction with the Wellcome Laboratories of Tropical Medicine, Beckenham, Kent.

Candidates must possess a first or second class (upper) honours degree from a UK Institution and will be expected to register for a higher degree.

Applications, including a full curriculum vitae and the names of two referees should be sent as soon as possible to:

Head of Paramedical Sciences  
Department Ref. CF111  
North East London Polytechnic  
Romford Road  
London E15 4LZ  
Tel: 01-555 0811, Ext. 66,  
from whom further information may be obtained. 2332(F)

# NELP

### UNIVERSITY OF LIVERPOOL

#### DEPARTMENT OF DENTAL SURGERY

#### ELECTRON MICROSCOPE UNIT

A research studentship is available for candidates holding or expecting to gain a 1st or 2(1) honours degree in a biological discipline.

The research programme of the unit is concerned with investigating the utilization of calcium and other elements in hard tissue forming cells by using electron microscopical analytical techniques.

Applications together with the names of two referees should be received as soon as possible by The Registrar, The University, PO Box 147, Liverpool L69 3BX. Quote Ref: RV/668. 2307(F)

### THE UNIVERSITY COLLEGE OF WALES ABERYSTWYTH DEPARTMENT OF AGRICULTURAL BOTANY MAFF STUDENTSHIP SYMBIOTIC NITROGEN FIXATION

Applications are invited from suitably qualified candidates to work on the ecology of *Rhizobium trifolii* with particular reference to the use of genetic markers and the ELISA technique.

The successful candidate must have at least an Upper Second Honours degree in Agricultural Botany or Microbiology and will be expected to study for a higher degree under the supervision of Dr D Gareth Jones. The ability to drive a car is desirable.

Application forms are available from the Registrar, University College of Wales, Aberystwyth, Dyfed. Closing date for applications 14 July 1979. 2330Z(F)

### THAMES POLYTECHNIC SCHOOL OF BIOLOGICAL SCIENCES

#### SRC CASE STUDENTSHIP

Applications are invited for a CASE studentship to undertake an investigation into the role of *Pseudomonas morsprunorum* lipopolysaccharide in cancer disease of cherries. The award is tenable from 1 October 1979.

Applicants should hold (or expect to obtain) a good honours degree in biochemistry or chemistry, and if in the latter, should preferably have some experience in microbiology. The investigation will be carried out in collaboration with East Malling Research Station, Maidstone, Kent, and will be jointly supervised by Dr A. R. W. Smith (Thames Polytechnic) and Dr R. C. Hignett (East Malling Research Station).

Further particulars and form of application may be obtained from the Staffing Officer, Thames Polytechnic, Wellington Street, London, SE18 6PF, to whom completed applications should be returned by 10 July 1979. 2285(F)

### SRC STUDENTSHIPS IONOSPHERIC RADIO WAVE PROPAGATION

Applications are invited for SRC CASE studentships leading to the PhD degree. The research programme involves basic studies in ionospheric physics, together with investigations of how this medium affects the performance of radio navigation and communications systems. The more applied topics involve considerable use of microprocessors.

Further details of these projects can be obtained from Dr. T. B. Jones, Physics Department, The University, Leicester LE1 7RH. 2317(F)

### PORTSMOUTH POLYTECHNIC

#### DEPARTMENT OF BIOLOGICAL SCIENCES

#### SRC CASE Studentships

Post 1 Title: The use of tree-rings as a means of dating timbers from historical sites.

Supervisor: Dr F. A. Hibbert.

Co-operating body: Department of Environment, Ancient Monuments Laboratory, London.

Post 2 Title: Microbial infestation of Diesel fuel storage delivery systems. Supervisors: Drs R. A. Eaton and E. B. G. Jones.

Co-operating body: Ministry of Defence, Central Dockyard Laboratory, Portsmouth.

#### SRC Studentship

Post 3 Title: Oogenesis in developmentally retarded tadpoles of *Xenopus laevis*.

Supervisor: Dr S. C. Turner.

Title: Some aspects of the biology of the larval stage of digeneans.

Supervisor: Dr T. A. J. Reader.

#### SRC Advanced Course

#### Studentships MSc COURSE IN THE BIODETERIORATION OF MATERIALS

A number of SRC awards are available for suitably qualified students who wish to apply for the above course.

Starting date for all posts October 1, 1979.

Applications to include a curriculum vitae and the names of two referees should be sent to the Administrative Assistant, Department of Biological Sciences, Portsmouth Polytechnic, King Henry I Street, Portsmouth PO1 2DY from whom further information can be obtained if desired.

Closing date for all applications: June 28, 1979. 2338(F)

### SCHOOL OF CHEMISTRY CASE AWARDS

Applications are invited for SRC/CASE studentships in the following areas of research:

a) "The Chemistry of Dihalogenocarbene Adducts of Terpenes" under the supervision of Dr. M. S. Baird and in collaboration with Bush Boake Allen Ltd.  
b) "Testing of pH glass electrodes at high temperatures" (Dr. A. K. Covington in association with Dr. P. O. Kane, ICI Mond Division, Runcorn, Cheshire). The project will be concerned with the extension of a new method of testing glass electrodes to higher temperatures (up to 130°C). It will provide a good training in industrial use and appraisal of electrochemical sensing devices.

c) "Spectroscopic Studies of Ammonium Urates". The project, to be carried out with UKAEA as the co-operating body, is designed to develop an understanding of the chemistry of the ammonium urate system. This understanding will assist the use of ammonium urate for the removal of uranium from solution. The study will involve spectroscopic studies of ammonium urates in particular using X-ray photoelectron spectroscopy. Under the supervision of Dr. P. M. A. Sherwood.  
d) "The Electrode Kinetics of Electron Exchange Reactions". The project is to study, under the supervision of Dr. J. A. Harrison, the reactions with metal ion complexes, metal deposition and electrocrystallisation phenomena at interfaces using the latest automated equipment. The kinetic information will be used to make correlations and predictions in allied technological fields (in conjunction with the International Nickel Co.).

All successful applicants will be registered for a PhD degree and grants will be in accordance with the current SRC Regulations.

Letters of application including the names of two referees should be sent to Mr. S. J. Hall, School of Chemistry, The University of Newcastle upon Tyne, NE1 7RU. 2277(F)

# university college of swansea

#### CASE Research Studentships

Applications are invited from candidates with upper second class honours degrees or equivalent, or from those expecting to obtain such a degree this Summer, for the following SRC (CASE Research Studentships) in the Department of Chemistry: (a) the use of borane-amine complexes in organic synthesis (Professor A. Pelter, in collaboration with ICI Pharmaceuticals Ltd.); (b) the synthesis of dihydroisocoumarins related to berberine (Dr. R. S. Ward, in collaboration with May and Baker Ltd.); (c) the synthesis of novel macrocyclic lactones with potential nervous system activity (Dr K. Smith, in collaboration with Pfizer Ltd.). Industrial grants are also available for work on gas chromatography and analytical chemistry. The value of the studentships will be in line with SRC awards. Further particulars may be obtained from Professor A. Pelter, Department of Chemistry, University College of Swansea, Singleton Park, Swansea, SA2 8PP. 2314(F)

### AGRICULTURAL RESEARCH COUNCIL STUDENTSHIP

Applications are invited for a studentship to work in the Protein Section of the Meat Research Institute.

The project is to investigate the turnover and remodelling of the connective tissues in relation to growth and development.

This will consist of radioactive incorporation studies together with autoradiography, the chemical analysis of connective tissue components and an examination of the cellular mechanisms for resorption of tissue.

The project is expected to form the basis for a PhD thesis in the University of Bristol and the appointment will commence in October, 1979.

Candidates should possess a First or Upper Second Class degree in Biochemistry.

Further particulars of the award and allowances together with Application Forms may be obtained from the Personnel Officer, Agricultural Research Council, Meat Research Institute, Langford, Bristol, BS18 7DY. 2347(F)

### SRC STUDENTSHIP DEPARTMENT OF PHARMACEUTICS

Applications are invited from graduates with first class or upper second class honours degrees in pharmacy or related disciplines for an SRC studentship for research in one of the following areas.

Solution properties of surfactants.

Activity of liposomes containing antibiotics.

Cell and tissue culture.

Please write stating interests to Professor A. T. Florence, Department of Pharmaceutics, University of Strathclyde, Glasgow G1 1XW.

2301(F)

## STUDENTSHIPS—continued

QUEEN MARY COLLEGE  
(University of London)SRC CASE  
RESEARCH STUDENTSHIP

Applications are invited for a research studentship, tenable for three years from October 1979, leading to the degree of MPhil/PhD of the University of London. The project is on the control of amylase production and secretion in yeast and will be jointly supervised by Professor E. A. Bevan and Dr Ivor Evans. It will involve physiological investigations as well as the application of advanced techniques of molecular genetics.

Candidates with, or expecting to gain, a first or upper second class honours degree in an appropriate subject should apply at once to Professor E. A. Bevan, Department of Plant Biology & Microbiology, Queen Mary College, Mile End Road, London E1 4NS, from whom further particulars can be obtained.

2345(F)

UNIVERSITY COLLEGE  
LONDON  
DEPARTMENT OF PHYSICS  
AND ASTRONOMY  
MULLARD SPACE SCIENCE  
LABORATORY  
Holmbury St. Mary  
Dorking Surrey

Applications are invited for a post-doctoral Research Assistantship financed by the Science Research Council for work on instrument development and on the analysis and interpretation of data in either of the Laboratory's two areas of research — X-ray astronomy and magnetospheric physics. The appointment will be for three years, commencing as soon as possible. Salary within the range of £4232 to £6627 plus USS membership.

Applications, with curriculum vitae and the names of two referees, should be sent to Professor R.L.F. Boyd, C.B.E., F.R.S., at the above address. 2366(P)

SUNDERLAND  
POLYTECHNIC  
FACULTY OF SCIENCE  
SCHOOL OF PHARMACY  
RESEARCH ASSISTANTS

Applications are invited from graduates possessing good honours degrees in pharmacy or other appropriate disciplines, or from undergraduates expecting to obtain such degrees this year. The successful applicants will be expected to work for a higher degree (MPhil/PhD) in one of the following fields:

- P1 — The effect of surfactant adsorption on drug release.
- P2 — The synthesis of potential drug molecules based on phloroglucinol.
- P3 — An investigation of the preparation and chemical, physical, and biological properties of phrazolopyridines.
- P4 — Chemotaxonomic and phytochemical investigations in the sub-family Aurantioideae (Rutaceae).
- P5 — A study of the migration of particles and droplets in a shear field.

The salary for an assistantship, which is normally tenable for up to three years, is £2,778 to £3,054 per annum (under review).

Applicants are requested to state the post(s) in which they are interested.

An application form and further details may be obtained from the Personnel Officer, Sunderland Polytechnic, Chester Road, Sunderland, SR1 3SD, and should be returned as soon as possible.

2267(P)

THE UNIVERSITY  
OF SHEFFIELDRESEARCH ASSISTANTSHIP  
IN  
THEORETICAL CHEMISTRY

The University expects shortly to be in a position to appoint a Postdoctoral Research Assistant, with support from the Science Research Council, for work in the general area of quantum chemistry with emphasis on Green's function and density functional methods. Appointment will be on Range 1A at up to £4910 p.a. Tenable three years subject to annual renewal, from 1 October 1979. Further information from Professor R. McWeeny, Department of Chemistry, the University, Sheffield S3 7HF. Quote ref: R327/G. 2358(P)

Applications are invited from suitably qualified science or dental graduates to work for a higher degree in one of the following fields of study currently in progress in the Department of Oral Biology, University of Alberta, Edmonton, Alberta, Canada.

Developmental Biology

Neurophysiology

Biochemistry of Connective Tissues

Calcium regulating hormones

Tumor Development

Graduate assistantships can be awarded to successful applicants.

Applicants can be directed to Dr. J. W. Osborn, Chairman, Department of Oral Biology, University of Alberta, Edmonton, Alberta, T6G 2N8, Canada. W190(P)

BIOCENTER  
(University of Basel)  
POSTDOCTORAL  
RESEARCH  
ASSISTANTSHIPS

One position is available immediately and one in mid-1980 to investigate mechanisms of *in ovo* oncogenesis induced by avian tumour viruses using various approaches to identify the *in vivo* target cells and the biochemical mechanisms of tumor induction. We are particularly interested in the infection of the chick embryo by tumor viruses in the early stages of embryonic development. Persons having experience in the area of modern embryology of the chick or mouse, using immunological, biochemical, histochemical or transplant technology will be preferred. Interested candidates please send curriculum vitae, bibliography, and the names of two referees to Prof. R. M. Franklin, Biocenter, University of Basel, Klingelbergstrasse 70, CH-4056 Basel/Switzerland. W194(P)

UNIVERSITY OF LONDON  
KING'S COLLEGE  
DEPARTMENT OF BIOPHYSICS  
RESEARCH  
ASSISTANTSHIP

Applications are invited for the post of research assistant to work on a Cancer Research Campaign — supported project concerned with the interactions of carcinogens and anti-cancer agents with nucleic acids. A degree in biochemistry, chemistry or related fields is required; experience in separation methods and/or handling of nucleic acids would be useful. Starting salary in the range of £3,775 to £4,333 + £502 London allowance. Appointment is for one year in the first instance, starting from October 1979, with the possibility of renewal for a further two years. Applications, with a curriculum vitae and names of two referees, to Dr S. Neidle, Department of Biophysics, King's College, 26-29 Drury Lane, London WC2B 5RL, from whom further particulars may be obtained. 2337(P)

## APPOINTMENTS WANTED

BIOLOGIST/MOLECULAR GENETICIST 26, Cambridge First, PhD Edinburgh in molecular genetics. Experienced in P3 recombinant DNA work, marine and terrestrial ecology (publications), humanistic psychology, amateur astronomy. Well travelled, seeks imaginative employment anywhere. Nick Hanscomb, Lamancha House, Lamancha, Peeblesshire. 2294(B)

## FELLOWSHIPS

UNIVERSITY OF  
NOTTINGHAM  
SCHOOL OF AGRICULTURE  
Sutton Bonington,  
Nr. LoughboroughDEPARTMENT OF PHYSIOLOGY &  
ENVIRONMENTAL STUDIES

Research opportunities in  
Environmental Science

1. A fellowship is available for a project supported by the ARC. This is concerned with the physics and economics of very low cost solar energy collectors for use in crop drying and the successful candidate will work with Dr. J. A. Clark and Mr. B. Wilton.

The appointment is for 3 years. Candidates should preferably have a PhD or equivalent experience in an appropriate branch of physics, engineering, or environmental science (salary scale commencing £4,776 p.a. at age 26). Applications will also be considered from newly qualified graduates with a good honours degree (salary scale commencing at £3,689 p.a.).

2. The Heat Balance of Wet Vegetation.

The duration of leaf wetness is an important factor influencing the development of plant diseases and the uptake of soluble pollutant gases. A PhD studentship is available for a study of micrometeorological processes which determine leaf wetness and to develop computer simulation models. A good honours degree in physics or environmental science is desirable. Candidates will work with Dr. M. H. Unsworth.

Further information may be obtained from the member of staff referred to and applications including a full curriculum vitae with the names and addresses of two referees should be submitted to them at the School as soon as possible. 2274(E)

POSTDOCTORAL  
FELLOWSHIPSTHE ROCHE INSTITUTE  
OF MOLECULAR BIOLOGY

Unusual opportunities are offered by the Roche Institute of Molecular Biology for postgraduate training and education. These postdoctoral fellowships are in the field of biochemistry, genetics, virology, neurobiology, pharmacology, and other areas of molecular biology. The Roche Institute, under the direction of Dr Sidney Udenfriend, is dedicated to basic research, and approximately 30 staff members enjoy independence in their choice and pursuit of research problems. Postdoctoral positions are now available in the departments of Physiological Chemistry & Pharmacology (Dr Sydney Spector, Chairman), Biochemistry (Dr Herbert Weissbach, Chairman), and Cell Biology (Dr Arthur Weissbach, Chairman). Fellowships at the Institute, which is located in Nutley, New Jersey, about 10 miles west of New York City, are awarded on an equal opportunity basis to recent recipients of an M.D., a Ph.D. or an equivalent degree in the biological or biochemical sciences. Stipends start at \$14,500 plus benefits. For further information, contact Dr George J. Cardinale, Roche Institute of Molecular Biology, Nutley, New Jersey 07110.

W195(E)

UNIVERSITY OF  
ST. ANDREWS  
RESEARCH FELLOWSHIP  
IN LASER PHYSICS

There is a vacancy for a Postdoctoral Research Fellow to work on a CO<sub>2</sub> TEA laser contract. Previous experience in laser physics and high vacuum technology would be an advantage.

Starting salary within the range £4,333 to £4,910 per annum (under review) plus USS; the appointment is tenable for two years in the first instance from October 1979.

Applications including a curriculum vitae and the names of two referees should be sent as soon as possible to Dr. A. L. S. Smith, Physics Department, University of St. Andrews, St. Andrews, Fife KY16 9SS, from whom further details can be obtained. 2295(E)

## EMBO

## European Molecular Biology Organization

LONG TERM FELLOWSHIPS IN MOLECULAR BIOLOGY  
AUTUMN 1979 AWARDS

Next deadline: August 31, 1979

EMBO long term fellowships are initially awarded for one year. Applications for a renewal for a second year and subsequently in cases of exceptional scientific merit for a third year are considered.

To be eligible a candidate must hold a doctors degree. Preference will be given to European and Israeli applicants wishing to work within Europe or Israel. EMBO long term fellowships are not, however, awarded for exchanges between laboratories within any one country. Applications for fellowships to be held outside Europe and Israel are considered but they have a lower priority, as do applications from non-European scientists wishing to work in Europe or Israel.

Successful applicants will be notified of their awards on October 29, 1979.

Further details and application forms may be obtained from Dr J. Tooze, Executive Secretary, European Molecular Biology Organization, 69 Heidelberg 1, Postfach 1022.40, F. R. Germany.

W188(E)

## FELLOWSHIPS continued

LIVERPOOL  
SCHOOL OF  
TROPICAL MEDICINE

Department of Parasitology

Applications are invited for a POSTDOCTORAL FELLOWSHIP to work on cultivation *in vitro* and moulting processes of filarial worms. A biochemical background with some experience of tissue culture techniques is desirable for this post. Appointment for one year to commence immediately. Starting salary £4,232 per annum, USS benefit.

Applications in the form of curriculum vitae and the names of two referees should be sent as soon as possible to the Head of Department of Parasitology, Liverpool School of Tropical Medicine, Pembroke Place, Liverpool L3 5QA.

2363(E)

UNIVERSITY OF EXETER  
CHEMISTRY DEPARTMENT  
Structural Studies  
of Liquid Crystals

Applications are invited for a Postdoctoral Research Fellowship to work with Professor A J Leadbetter on X-ray diffraction studies of smectic liquid crystals. Crystal structure determinations of the crystalline precursors and some neutron scattering work might also be involved depending on the interests and experience of the person appointed. Applicants may be chemists or physicists and some experience of X-ray diffraction and computing would be an advantage, though not essential.

The post is tenable for one year in the first instance with the possibility of renewal for a further year. Starting date by arrangement on or after 1 September 1979 at a point on the salary scale commencing at £4,333 pa, depending on age and experience.

Applications should be sent as soon as possible to Professor A J Leadbetter, Department of Chemistry, Stocker Road, Exeter.

2311(E)

## UNIVERSITY OF BRISTOL

VETERINARY  
RESEARCH FELLOWSHIP

Applications are invited from veterinary graduates for a Research Fellowship to investigate the physiology of cervical dilatation in the ewe. The successful applicant will join a research group in the Department of Anatomy which is currently working on problems of the myometrium and the physiology of relaxin. The group has accommodation for sheep at Bristol and at the School of Veterinary Science, Langford. It is intended that the applicant will employ a variety of research techniques in the elucidation of this problem, including chronic recording of cervical softening *in vivo*. The opportunity exists to investigate the histochemistry of the glycosaminoglycans of the cervix. In addition, the Department offers a wide spectrum of facilities and expertise in electron-microscopy, electro-physiology, polypeptide biochemistry, neurophysiology, hard tissue studies, and experimental surgery.

The Fellowship is provided by the Agricultural Research Council and awards a salary of £4,232 to £8,452 depending upon age and experience. The appointee will be expected to register for a higher degree.

Applications in duplicate which should include a full curriculum vitae together with the names and addresses of two referees should be sent to Professor D. G. Porter, Pre-Clinical Veterinary Studies, Department of Anatomy, The Medical School, University of Bristol, Bristol BS8 1TD.

2248(E)

ALL SOULS COLLEGE  
RESEARCH FELLOWSHIP

The College intends to make an election to a Research Fellowship in the course of the academic year 1979-80. It is anticipated that the election will be made in or about February 1980.

The Research Fellowship will be tenable for a period of seven years. The College would normally renew the Fellowship if there is evidence of satisfactory achievement. The retiring age is 67. The stipend payable is related to the age of the Fellow upon appointment.

The Fellowship will be open to those working in the following fields of study: Law, History, Philosophy, Politics, Economics, English, Classics and Mathematical Sciences.

The Fellowship is open to men and women. (It is assumed that Privy Council approval will shortly be forthcoming for an amendment to the Statutes opening membership of the College to women.)

Further particulars, including salary and terms of appointment, may be obtained from The Warden's Secretary, All Souls College, Oxford. Applications, which should contain the names of not more than three referees, must reach the Warden not later than 1 October 1979, and should be marked "Research Fellowship".

2282(E)

THE UNIVERSITY OF HULL  
DEPARTMENT  
OF APPLIED PHYSICS

Applications are invited for two research fellowships, which are immediately available, for a period of up to three years.

Department of Applied Physics 1. A research fellow is required to measure the frequency characteristics of the current generation of pulsed CO<sub>2</sub> lasers and to devise ways of improving their frequency stability using techniques such as hybridisation and injection locking.

2. A research fellow is required to work on the use of tunable multi-atmosphere, molecular gas lasers for the remote sensing of trace gases in the atmosphere.

These fellowships are suitable for graduates in Physics, Applied Physics or Electronic Engineering with at least three years research experience in relevant fields.

Salary: At an appropriate point on the scale £4,333 to £7,521 per annum. (From 1st October)

Applications should give full details of education, qualifications and research experience, together with the names of two referees, and should be sent by 27th July 1979 to Dr. E. L. Thomas, Department of Applied Physics, the University of Hull, Hull, HU6 7RX from whom further details may be obtained.

2350(E)

RESEARCH FELLOWSHIP  
IMPERIAL CANCER  
RESEARCH FUND

We have a vacancy for a post-doctoral Research Fellow to join a group working on ageing and neoplastic transformation in epithelial cell systems *in vitro*. Special experience in cell culture techniques, cell hybridisation, etc., an advantage.

Appointment will be for three years. Salary according to qualifications and experience.

Further information from Dr L. M. Franks (01-242 0200, ext. 211). Applications with curriculum vitae and names of two referees should be sent to The Secretary, Imperial Cancer Research Fund, Lincoln's Inn Fields, London WC2A 3PX.

2250(E)

LA TROBE UNIVERSITY  
Melbourne, Australia  
LA TROBE

## RESEARCH FELLOWSHIP

Applications are invited for a La Trobe Research Fellowship. Applicants should be at the recent (within the last five years) postdoctoral level and the Fellowship will normally be awarded to an applicant with research experience away from La Trobe University. The successful applicant must hold a doctoral degree or have equivalent qualifications at the time of commencement of the Fellowship.

The Fellowship will be awarded initially for a period of 12 months and may be renewed for a further maximum period of 12 months. Applicants must be able to take up the Fellowship no later than 30 June 1980.

Salary is \$A15,786 per annum.

Further information and application forms are available from the Graduate Studies Officer. Enquirers should indicate the research discipline of interest to them. The closing date for applications is 31 August 1979. D D Neilson, Registrar, Bundoora, Victoria 3083, Australia.

2321(E)

## CONFERENCES

EUROPEAN SOCIETY FOR  
COMPARATIVE SKIN  
BIOLOGY

Symposium on Surface Eco-systems, Ayr, Scotland, September 13, 14, 1979. International Conference, including symposium on Insect Cuticle, Copenhagen, August 25-28, 1980. Details from Dr P. E. Budtz, August Krogh Institute, 13 Universitetsparken, Copenhagen, Denmark.

2281(C)

## ASSOCIATESHIPS

UNIVERSITY OF  
CAMBRIDGEDEPARTMENT OF THEORETICAL  
CHEMISTRY

A post-doctoral research associateship is available for two years to develop a new method of computing correlated relativistic atomic wavefunctions with the aim of investigating the electronic structure of actinide and superheavy elements. Applications including a curriculum vitae and the names and addresses of two referees should be sent as soon as possible to Dr N. C. Pyper, University Chemical Laboratory, Lensfield Road, Cambridge, CB2 1EW.

2336(O)

## COURSES

UNIVERSITY OF LEICESTER  
MSc in Experimental  
Space Physics

Applications are now being considered for the Space Physics course for entry in October. Candidates should have a degree with 1st or 2nd class honours in Physics, Mathematics or Engineering. The course runs for 12 months and includes lectures, dissertation and project work covering both scientific (astronomy, earth sciences applications) and technical (propulsion orbits, communications, etc) aspects of present-day space research. A number of SRC studentships are available to successful applicants.

Write for further details, including the names and addresses of two academic referees, to Professor K A Pounds, Department of Physics, University of Leicester, Leicester LE1 7RH.

2283(D)

## AWARDS

IMPERIAL  
COLLEGE

DEPARTMENT OF CHEMISTRY SRC/CASE awards from October 1st 1979, are available for suitably qualified graduates in the following areas, with the supervisors and industrial sponsors indicated:

1. Development of modified electrodes for electrocatalysis (Professor W. J. Albery, I.C.I., Mond Division).
2. Development of electrochemical sensors for power station waters (Professor W. J. Albery: Central Electricity Research Laboratory).
3. Application of microprocessors to electroanalytical techniques (Professor W. J. Albery: Laboratory of the Government Chemist).
4. Alkali-metal peroxy-salts (Drs. W. P. Griffith and A. C. Skapski: Interlox Chemicals Ltd.).
5. Absorption of organic molecules in zeolites from liquid-phase solutions (Dr. L. V. C. Rees: Laporte Industries Ltd.).
6. Binary and ternary ion-exchange equilibria and kinetics in zeolites (Dr. L. V. C. Rees: Procter and Gamble Ltd.).

Applications should be addressed to the supervisors named, at Chemistry Department, Imperial College, London SW7 2AY, as soon as possible: telephone enquiries to 01-589 5111 are welcome.

2322(N)

## LECTURES

THE  
EXPERIMENTAL PSYCHOLOGY SOCIETY

The Seventh Sir Frederick Bartlett Lecture will be delivered by Professor M. I. Posner, of the Department of Psychology, University of Oregon.

## ORIENTING OF ATTENTION

5.30 pm, Thursday July 5th, 1979.

Main Lecture Theatre,  
Department of Experimental Psychology,  
University of Oxford.

The lecture will be open to the public.

## Happy Endings.

Your DNA research should have a happy ending. That's why Miles has developed enzymes that cleave and splice DNA easily and accurately.

All of our restriction nucleases—such as *Eco* RI—specifically cleave DNA within certain well-defined base sequences. And to make sure you're happy with the cleaved ends, we include a sample of lambda DNA for verification of enzyme activity... so you never risk your research DNA. The results of our stringent specification tests are reported on the chemical

credential that accompanies each order. No surprises, no mystery.

And, for recombinant DNA, we have terminal transferase to add dA and dT segments and DNA ligase to splice fragments together.

Restriction nucleases, terminal transferase, DNA ligase. Miles enzymes for happy endings... and beginnings.

Please supply more information about

☐ Restriction nucleases ☐ DNA ligase ☐ Terminal transferase

☐ Please send a current Miles Biochemical Catalog.
